LABOR-MANAGEMENT DATA

MAJOR COLLECTIVE BARGAINING DATA are obtained from contracts on file at the Bureau of Labor Statistics, direct contact with the parties, and from secondary sources. Additional detail is published in *Current Wage Developments*, a monthly periodical of the Bureau. Data on work stoppages are based on confidential responses to questionnaires mailed by the Bureau of Labor Statistics to parties involved in work stoppages. Stoppages initially come to the attention of the Bureau from reports of Federal and State mediation agencies, newspapers, and union and industry publications.

Definitions

Data on wage changes apply to private nonfarm industry agreements covering 1,000 workers or more. Data on wage and benefit changes *combined* apply only to those agreements covering 5,000 workers or more. **First-year wage settlements** refer to pay changes going into effect within the first 12 months after the effective date of the agreement. **Changes over the life of the agreement** refer to total agreed-upon settlements (exclusive of potential cost-of-living escalator adjustments) expressed at an average annual rate. **Wage-rate changes** are expressed as a percent of straight-time hourly earnings, while **wage and benefit changes** are expressed as a percent of total compensation.

Effective wage-rate adjustments in major bargaining units measure actual changes during the reference period, whether the result of a newly negotiated increase, a deferred increase negotiated in an earlier year, or a cost-of-living adjustment. Average adjustments are affected by workers receiving no adjustment, as well as by those receiving increases or decreases.

Work stoppages include all known strikes or lockouts involving 1,000 workers or more and lasting a full shift or longer. Data cover all workers idle one shift or more in establishments directly involved in a stoppage. They do not measure the indirect or secondary effect on other establishments whose employees are idle owing to material or service shortages.

32. Wage and benefit settlements in major collective bargaining units, 1977 to date

How to order BLS publications

PERIODICALS

Order from (and make checks payable to) Superintendent of Documents, Washington, D.C. 20402. For foreign subscriptions, add 25 percent.

Monthly Labor Review. The oldest and most authoritative government research journal in economics and the social sciences. Current statistics, analysis, developments in industrial relations, court decisions, book reviews. $23 a year, single copy $3.50.

Employment and Earnings. A comprehensive monthly report on employment, hours, earnings, and labor turnover by industry, area, occupation, et cetera. $31 a year, single copy $3.75.

Occupational Outlook Quarterly. A popular periodical designed to help high school students and guidance counselors assess career opportunities. $8 for four issues, single copy $2.75.

Current Wage Developments. A monthly report about collective bargaining settlements and unilateral management decisions about wages and benefits; statistical summaries. $14 a year, single copy $2.50.

Producer Prices and Price Indexes. A comprehensive monthly report on price movements of both farm and industrial commodities, by industry and stage of processing. $20 a year, single copy $3.25.

CPI Detailed Report. A monthly periodical featuring detailed data and charts on the Consumer Price Index. $20 a year, single copy $3.50.

PRESS RELEASES

The Bureau's statistical series are made available to news media through press releases issued in Washington. Many of the releases also are available to the public upon request. Write: Bureau of Labor Statistics, Washington, D.C. 20212.

Regional. Each of the Bureau's eight regional offices publishes reports and press releases dealing with regional data. Single copies available free from the issuing regional office.

BULLETINS AND HANDBOOKS

About 140 bulletins and handbooks published each year are for sale by regional offices of the Bureau of Labor Statistics (see inside front cover) and by the Superintendent of Documents, Washington, D.C. 20402. Orders can be charged to a deposit account number or checks can be made payable to the Superintendent of Documents. Visa and MasterCard are also accepted; include card number and expiration date. Among the bulletins and handbooks currently in print:

Occupational Outlook Handbook, 1980–81 Edition. Bulletin 2075. A useful resource supplying valuable assistance to all persons seeking satisfying and productive employment. $9, paperback; $12, cloth cover.

Employment Trends in Computer Occupations. Bulletin 2101. October 1981. Results of a BLS study of employment of workers in five computer-related occupations. $3.50.

National Survey of Professional, Administrative, Technical, and Clerical Pay, March 1981. Bulletin 2108. Summarizes the results of the Bureau's annual salary survey for 23 occupations. Data for purchasing assistants and photographers published for the first time. $4.75.

Occupational Projections and Training Data. Bulletin 2052. Presents both general and detailed information on the relationship between occupational requirements and training needs. (Updates Bulletin 2020.) $5.50.

Exploring Careers. Bulletin 2001. A new career guidance resource designed for junior high school students but useful for older students as well. Includes occupational narratives, evaluative questions, suggested activities, career games, and photographs. $11.

Industry Wage Survey: Life Insurance, February 1980. Bulletin 2119. A summary of the results of a survey of occupational wages and employee benefits in home and regional offices of life insurance carriers in February 1980. $3.25.

Major Collective Bargaining Agreements: Plant Movement, Interplant Transfer, and Relocation Allowances. Bulletin 1425–20. Information regarding three important issues in collective bargaining. $5.50.

Perspectives on Working Women: A Databook. Bulletin 2080. Presents comprehensive statistics on characteristics of working women. Topics covered in 100 tables and brief text include extent of work experience, marital and family status, education, earnings, occupations, and race and Hispanic ethnicity. (Updates Bulletin 1977.) $5.00.

Economic Projections to 1990. Bulletin 2121. An anthology of five articles published in the *Monthly Labor Review* on the subject of alternative patterns of economic growth through this decade and the next. Includes supplementary tables. $6.00.

REPORTS AND PAMPHLETS

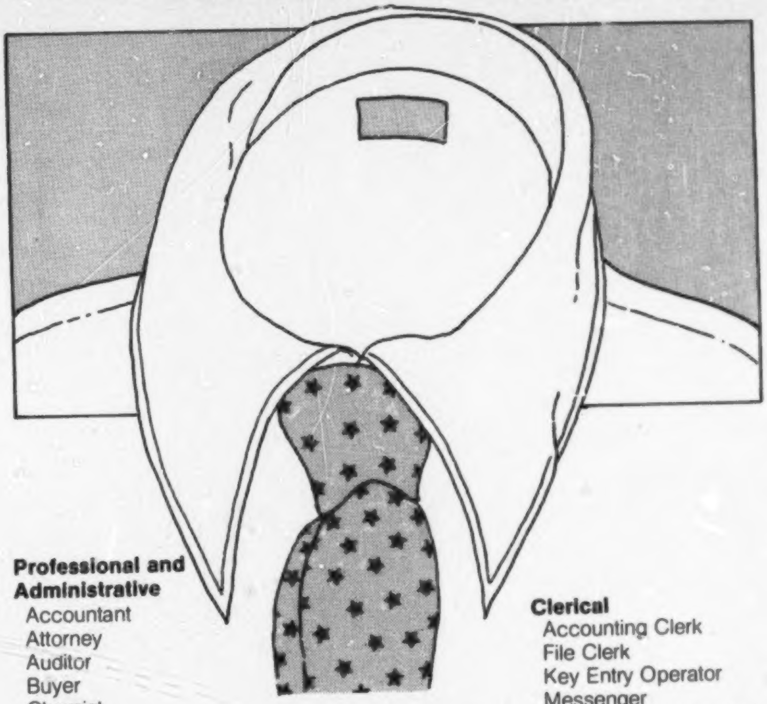
Single copies available free from the BLS regional offices or from the Bureau of Labor Statistics, U.S. Department of Labor, Washington, D.C. 20212.

Major Programs of the Bureau of Labor Statistics. Report 552. A summary of the Bureau's principal programs, including data available, sources, uses, and publications.

How to Get Information from the Bureau of Labor Statistics. An explanation of what materials are available from the Bureau of Labor Statistics and the prices of each publication. Included is information on the scope of BLS statistics.

A Report on White-Collar Salaries by Occupation

from the Bureau of Labor Statistics



The 22nd in an annual series, the **"National Survey of Professional, Administrative, Technical, and Clerical Pay, March, 1981,"** provides nationwide salary averages and distributions for 96 work level categories covering 23 occupations. Data for purchasing assistants and photographers are published for the first time. The occupations include:

Professional and Administrative
- Accountant
- Attorney
- Auditor
- Buyer
- Chemist
- Chief Accountant
- Director of Personnel
- Engineer
- Job Analyst
- Public Accountant

Technical Support
- Computer Operator
- Drafter
- Engineering Technician
- Photographer

Clerical
- Accounting Clerk
- File Clerk
- Key Entry Operator
- Messenger
- Personnel Clerk/Assistant
- Purchasing Assistant
- Secretary
- Stenographer
- Typist

Also included are salary data from 1970, a description of survey methods and scope, survey changes in 1981, occupational definitions, and a comparison of average annual salaries in private industry with Federal Classification Act salary rates.

Order Form

Please send______copies of "National Survey of Professional, Administrative, Technical, and Clerical Pay, March 1981," Bulletin 2108. Stock no. 029-001-02629-3, price $4.75.**

MONTHLY LABOR REVIEW

JUNE 1982
VOLUME 105, NUMBER 6

Henry Lowenstern, Editor-in-Chief
Robert W. Fisher, Executive Editor

Jerome A. Mark 3 **Measuring productivity in service industries**
The growth of the service economy presents special challenges for productivity analysts; output is often difficult to quantify, and measurement of labor input requires great care

R. Gillingham, W. Lane 9 **Changing the treatment of homeownership in the CPI**
In 1983, the treatment of housing in the CPI will begin changing to reflect only the cost of shelter services of owner-occupied housing, rather than investment aspects

Carol M. Utter 15 **Labor turnover in manufacturing: the survey in retrospect**
The discontinued Federal-State series shows that the level of hires, quits, and other job changes has remained relatively stable except for cyclical variations

Carol Boyd Leon 18 **Occupation winners and losers: who they were during 1972–80**
Job gains occurred in most occupational groupings in which Americans were employed during the 1970's; almost half of the increase occurred in just 20 of 235 occupations

Diane Nilsen Westcott 29 **Blacks in the 1970's: did they scale the job ladder ?**
More blacks obtained white-collar jobs, but fewer penetrated higher-salaried positions; mobility in the higher-paid blue-collar jobs proved to be somewhat more impressive

Henry P. Guzda 39 **Labor Department's first program to assist black workers**
The philosophy of equal opportunity began with the Division of Negro Economics, created during World War I, but the project was ahead of its time and did not survive

Labor Month In Review

UP AND DOWN. Two recent reports of the Bureau of Labor Statistics indicate that the proportion of women participating in the labor force continues to rise while at the same time the participation of students appears to be slackening. Some excerpts:

Women up. Even with the slowdown in economic activity, 1.1 million more women were in the labor force in the fourth quarter of 1981 than a year earlier, and their participation rate advanced to 52.2 percent. Over the 1-year period, the number of women with jobs grew by 700,000 with most of this gain occurring in the early part of the year. As the year progressed and economic conditions deteriorated, the number of unemployed women rose by more than 400,000, causing their jobless rate to climb from 7.7 to 8.5 percent. However the rate for men rose even faster, as they were more concentrated in manufacturing jobs where layoffs have been especially severe. By December, the unemployment rate for men (9.1 percent) exceeded that for women (8.6 percent).

Although most women in the United States live in families, about 14.9 million, or 17 percent of all women 16 years old and over, were not living in a family during the third quarter of 1981. They were either living alone (12.5 million), or sharing living quarters with persons not related to them (2.4 million). More than half of those living alone were 60 years of age and over, with widows dominating. About 46 percent of women living alone were in the labor force. By contrast, women living with nonrelatives were much younger; nearly two-thirds were 20 to 34 years old. They were also much more likely to be working. About 76 percent were in the labor force during the third quarter.

The women who live with persons other than relatives were more than twice as likely as those living alone to be unemployed. More than 1 of every 10 were jobless compared with less than 1 of 20 of their counterparts living alone. About one-fifth of all jobless women not living in families had been unemployed for 15 weeks or more.

Students down. Labor force activity among students 16 to 24 years old edged down over the year ended in October 1981. This was the third year in a row in which labor force participation, which had risen substantially through the 1960's and most of the 1970's, fell.

The unemployment rate for students edged up from 13.7 to 14.4 percent between October 1980 and October 1981. Moreover, recent data on students 16 to 21 indicate further increases in unemployment and a continued slackening in labor force activity since the special survey of October 1981.

From October 1980 to October 1981, labor force participation rates among youth enrolled in school declined from 47.8 to 46.7 percent for men and from 47.0 to 45.7 percent for women. For youth no longer enrolled in school, labor force participation over the year showed little change. Since 1960, the participation rate for men 16 to 24 and no longer in school has drifted down from 95.0 to 91.7 percent. At the same time, the rate for women in this group has risen dramatically, from 50.2 to 73.0 percent, largely reflecting changes in marital and childbearing patterns, increases in demand for white-collar and service workers, and new legislation concerning work opportunities.

For both students and nonstudents, labor force participation patterns by race and Hispanic origin were similar in October 1981 to those that have prevailed for many years. Among students, whites had the highest rate (49.4 percent), followed by Hispanics (38.1 percent) and blacks (28.2 percent). Among youth not in school, the rates were considerably higher, but the order was the same.

A record 1.6 million youth who graduated from high school in 1981 were attending college in October 1981. Some 54 percent of all recent graduates were enrolled, compared with 49 percent a year earlier. The labor force participation rate of the new college students was 43.7 percent, substantially higher than in the early 1970's.

A large proportion of recent high school graduates who did not go on to college were in the labor force in October. At 84 percent, their labor force participation rate was higher than in the early 1970's, mostly because of the increase in the rate for women, which advanced from 69 percent in 1970 to 81 percent in 1981. In both years, almost 1 in 4 of the female graduates in the labor force were unemployed.

The number of recent high school dropouts declined over the year, reflecting the general decrease in the number of young teenagers in the population. Youth who dropped out of high school between October 1980 and October 1981 were much less likely to be in the labor force than their classmates who had graduated but had not enrolled in college. The unemployment rate for dropouts (36.4 percent)—a relatively small youth group—has always been volatile; over the year, it climbed sharply for women while remaining about the same for men.

Additional information may be found in *Employment and Perspective: Working Women, Fourth Quarter 1981* (BLS Report 657), and in the Department of Labor release USDL 82-175. An article on participation of students in the work force will appear in an upcoming issue of the *Review*. □

Measuring productivity in service industries

The growth of the service economy presents special challenges for productivity analysts; output is often difficult to quantify, and measurement of labor input requires great care

JEROME A. MARK

The increased importance of service industries over the last two decades and current concern over productivity growth have stimulated interest in productivity measures for this expanding sector of the economy.

The service sector, as defined here, encompasses the major industry groupings of trade, finance, insurance, communications, public utilities, transportation, and government, as well as business and personal services. It accounts for almost three-fourths of the Nation's employment and provides the greatest potential, as well as some of the greatest difficulties, for developing productivity measures.

Over the last decade, the Bureau of Labor Statistics has been expanding the number of service industries for which it publishes productivity measures, and at present provides measures for 16 industries, representing almost a third of the employment in the sector. The Bureau is continuing to develop additional measures, and hopes eventually to extend coverage to most of the service sector.

This article describes that effort, discusses some of the problems of measuring productivity, particularly labor productivity in service industries, and explains how the Bureau is working to resolve some of the problems.

Linking output to input

Productivity measures relate real physical output to real input. They range from single factor measures, such as output per unit of labor input or output per unit of capital input, to measures of output per unit of multifactor input. Such measures also reflect changes in technology, scale of production, educational levels of workers, managerial techniques, and many other factors in addition to the contributions of the particular inputs.

Although BLS is currently developing multifactor productivity measures, at present, the published productivity measures relate output to labor input. This is the most extensively developed and widely used productivity measure because of its relevence to economic analyses and because, as a practical matter, labor is the most easily measured input.

Problems of measuring output

In many ways, the problems of measuring output in the service industries are similar to those of measuring output in the goods-producing industries. That is, the output indicator must be quantifiable and independent of the input measures. If an output measure for an activity is based on an input measure, as is the case in some instances in the national accounts, obviously no change in productivity can be ascertained. In the case of general government, for example, output in the national

---

Jerome A. Mark is Assistant Commissioner for Productivity and Technology, Bureau of Labor Statistics.

income and product accounts is measured in terms of compensation of government employees. The deflated or constant-dollar measure is derived from changes in employment. Hence, changes in the output measure are closely related to changes in the input measure.

It is also important to distinguish between intermediate and final services. In productivity measurement, we attempt to ensure that the indicators represent output flowing from the industry being measured rather than intermediate steps in the service flow. In this sense, productivity measurement differs from work measurement, which generally refers to the analysis of the operation of an activity and the labor requirements at each intermediate stage. Productivity measurement refers only to the final service and its relationship to input.

For example, in the trucking industry, a count of the ton-miles of freight moved would be the appropriate indicator of the final output—that is, the result of all the activities of the industry. The intermediate steps, such as pickup and delivery, platform work, billing, and collecting, are considered to be subsumed in the final output.

In the case of an organization or an industry providing one type of service, output is merely a count of the units of this service, however defined. In the more usual case of an industry producing a number of heterogeneous services, the various units must be expressed in some common basis for aggregation. For example, the output of franchised new-car dealerships should be a combination of the number of cars sold and the repair activities of the dealers, with appropriate weighting.

To obtain a productivity measure that is an average of the changes of individual components, the appropriate weights for combining the various elements in the output measure are in terms of their factor input requirements. In a labor productivity measure, the weights are unit labor requirements.

Homogeneity among services, after considerations of quality and specifications, is indicated by similarity in unit labor requirements. In this way, the output measure for the development of labor productivity statistics differs from more traditional production measures based on total price or value-added price weighting.

When there are quality changes within the service, adjustments must be made in the output measure to account for the fact that the output is no longer the same homogeneous unit. However, the indicator of quality change for labor productivity measurement differs from the usual concept of quality change associated with consumer price measurements in that it reflects differences in producers' labor requirements or labor costs rather than consumer utility differences.

Ideally, then, the output measure should incorporate data on the number of services provided, differentiated by unit labor requirements, and in sufficient detail to adjust for quality changes. In practice, however, such data are not generally available for service industries (and, in many cases, for goods-producing industries as well). As a result, approximations based on alternative approaches must be used.

The principal alternative is to remove the change in price from the change in total value of the volume of services. This approach is tantamount to price weighting quantities of services provided. Insofar as price relationships among the various component services of a service industry are similar to the unit labor requirements or unit labor costs, this is a close approximation of the desired measure. And because it is easier to measure price change for a specified group of services than it is to measure the number of services provided directly, this is the approach most generally followed.

However, the adjustment requires data in sufficient detail to adequately represent the price trends of the components included in the price change. Otherwise, price movements of the covered areas will be implicitly imputed to the uncovered areas. But because the relationship among the price movements of similar services is much stronger than the relationship among quantity changes, this alternative still has greater viability than imputing quantity changes for uncovered services.

In practice, BLS uses the two approaches to develop output measures for service industries. In some instances, quantity data are available, particularly for utilities and transportation industries. In others, price deflation is employed, and for some, deflation at lower levels of aggregation is combined with labor input weighting at higher levels. For example, in developing the measure for gasoline service stations, gasoline sales, repair, and other services are deflated separately and summed, but in the case of retail food stores, sales by major department are deflated and combined with employee labor cost weights.

Measuring labor input

With regard to labor input measures, the principal problems are data gaps. Information is needed on hours worked by all persons—nonsupervisory workers, supervisory workers, and self-employed and unpaid family workers—in an individual industry. But although data on hours worked are collected by various government agencies as part of such ongoing programs as the Bureau's occupational safety and health surveys, they tend to be limited in scope, or otherwise inconsistent with the output data developed.

The principal source of data on employment and hours is the BLS Current Employment Survey of establishments. This payroll series provides good measures of the employment and hours of nonsupervisory workers. However, it is collected on an hours paid basis, rather than on an hours worked basis. To the extent that hours paid for but not worked are changing, this measure has limitations. To overcome this problem, the Bureau is measuring hours at work as a proportion of hours paid for a sample of establishments in the survey and will use these data to adjust the industry hours paid series.

In general, data on the hours of supervisory workers are poor. Although employment data on supervisory workers are available from the payroll survey, hours data are not. Other sources, such as the censuses of population, are used to estimate this component of the labor input measure.

Data on the number of self-employed, an important component of the input series measure for retail industries, come from the Internal Revenue Service (IRS). The IRS data lag current estimates by 3 years, but may be projected forward with special tabulations from the Current Population Survey (CPS).

These CPS tabulations break out the numbers and hours of self-employed and unpaid family workers at the 3-digit Standard Industrial Classification level. Although the sample size at this level is small and the statistical error is high, the data are the only continuous series of the number and hours for unpaid family workers and for the hours of the self-employed.

The measures derived from these data are unweighted hours; that is, the hours of various types of employees are treated as being equally productive. This would not be a problem if the proportions of workers at different levels of productivity were constant over time. However, to the extent that there are changes in the composition of the work force, such as age, sex, and occupational mix, it may be desirable to adjust the labor input measure for these changes which otherwise would be reflected in the productivity measure.

Data gaps hamper the making of these adjustments. Industry data on employment and hours by age and occupation are limited, although various sources, such as the CPS and BLS occupational employment surveys, provide some pieces. And while worker groups may be differentiated into productivity levels according to their wages or compensation, pay is a factor which may reflect other than productivity differences.[1]

Measures for service industries

At present, BLS publishes indexes of output per unit of labor input for industries in each major service activity—trade, communications, transportation, utilities, and business and personal services, a total of 16 separate measures. Data for these industries, presented in table 1, indicate a wide range of productivity growth since 1973, the year in which a productivity slowdown for the general business economy appeared to begin. In many cases, the growth rates exceeded those for industries in the goods-producing sector.

Table 1. Average annual rates of change in output per hour of all employees in selected service industries, 1965–73 and 1973–80

[In percent]

SIC Code	Industry	1965-73	1973-80
	Transportation:		
401	Railroad transportation, revenue traffic	4.2	2.2
4111;4131;414 (parts)	Bus carriers	-1.5	-0.4
4213 (parts)	Intercity trucking[1]	2.7	0.5
4511	Air transportation[1]	5.3	4.3
4612,13	Petroleum pipelines	7.9	0.0
	Communications:		
4811	Telephone communications	4.7	7.0
	Public utilities:		
491;492;493	Gas and electric utilities	4.9	0.7
491;493 (part)	Electric utilities	5.4	1.3
492;493 (part)	Gas utilities	3.9	-0.4
	Trade:		
54	Retail food stores	2.2	-1.2
5511	Franchised new car dealers	2.6	0.5
5541	Gasoline service stations	4.9	3.1
58	Eating and drinking places	1.1	-1.0
5912	Drug and proprietary stores	6.2	1.9
	Services:		
7011	Hotels, motels, and tourist courts	1.8	1.3
721	Laundry and cleaning services	1.7	-1.1

[1] Output per employee.

In addition, a measure for commercial banking is being developed, and work has begun on measures for the insurance and hospital industries. In a related area, productivity measures for Federal agencies which provide functions such as recordkeeping, insurance, libraries, building and grounds maintenance, and medical services have been published.

It is not possible within the confines of this article to discuss all of the productivity measures prepared by the Bureau, but reference to some of the more important and interesting ones in each of the major areas can illustrate the difficulties encountered in constructing such statistics.

Trade. The Bureau has published measures for retail trade industries since 1975 (with the data beginning in 1958). At present, statistics are published for five important industries—retail food stores, new car dealerships, gasoline service stations, eating and drinking places, and drugstores. Work is underway on a measure for apparel stores, including shoe stores, to be published separately. The effort to develop productivity measures in the wholesale area has not yet succeeded.

For most retail trade industries, data on gross sales in current dollars, deflated by the appropriate price indexes, are used to estimate real output. This method, as mentioned earlier, can yield good estimates of real output. However, such measures can reflect shifts among services with different values, but having the same labor requirements. Therefore, the overall industry productivity index can show movements without any change in component elements.

In retail industries, a large portion of the value of sales has been provided by the manufacturer and the wholesaler of the product sold. A net output measure would be desirable, because it would most closely correspond to the value added by the retailer. However, a gross or total sales measure will yield the same results as a net or value-added measure if the value added as a percent of sales (gross margin) does not change over time. Available data indicate that, among retail industries for which productivity data are published, gross margins have not changed significantly over time.

To incorporate labor input weights, the indexes for most of the retail trade industries are developed in two stages. First, deflated output measures based on sales volume are developed for detailed merchandise lines. These are aggregated to higher levels and then combined with labor costs weights. For example, in retail food stores, sales for 13 key merchandise lines are deflated using specially prepared price indexes based on CPI components. The merchandise lines are aggregated to five department lines—meat, produce, frozen food, dry groceries, and dairy and all others. These are then aggregated with labor cost weights from Department of Agriculture data to develop the overall output measure for groceries. The labor input data for retail trade productivity statistics are generally derived from the Bureau's establishment survey, supplemented by IRS and CPS data.

Transportation. BLS publishes productivity measures for five transportation industries—railroads, intercity trucking, intercity buses, air transportation, and petroleum pipelines. These measures cover 57 percent of transportation employment.

Conceptually, productivity measures for the transportation industries are easier to develop than those for other non-goods producing industries. This is because transportation industry output—the movement of goods or passengers or both from one point to another—is more easily quantified. Output units in transportation have two dimensions, amount and distance; they reflect not only how much has been transported, but also how far. As such, ton-miles, passenger-miles, barrel-miles, and so forth are the primary output indicators for these industries.

Although the basic information for developing good transportation productivity measures is available and is, of course, being used, there are some data gaps that place certain limitations on the BLS measures. For example, it is sometimes impossible to adjust the productivity measures adequately for changes in the average length of haul. The unit labor requirements associated with the movement of goods and passengers are usuall greater for short hauls than for long hauls. Therefore, shift from a long haul to a short haul trip or vice vers could be reflected as a change in productivity althoug only the mix of trips had changed.

For the two major freight-carrying industries, railroads and trucking, undifferentiated ton-mile information is reported for total freight operations. In trucking the ton-mile data are also reported separately for thre types of carriers—general, contract, and others. Bu output measures should reflect the *kinds* of commoditie handled and the average distance they are moved. Th preferred way to develop these measures would be t combine the tonnage and the average haul of each commodity by its respective labor requirements and aggregate the results for all commodities transported. Unfortunately, this cannot be done with available data.

However, supplementary information on tonnage fo railroads is available from the ICC for about 200 commodity lines, ranging from agricultural and mining products to motor vehicles and scientific instruments. Until recently, similar information was also availabl for the trucking industry. BLS uses these data to adjust the overall measure of freight ton-miles for changes in the composition of goods carried.

Although this commodity adjustment is a significant improvement, refinements to the undifferentiated ton-miles cannot be developed to the extent desired. For example, separate labor requirements data are not available for weighting the individual commodity groups. The commodity index adjustments are therefore made in terms of unit revenue weights, the underlying assumption being that differences between labor requirements among commodities are similar to differences in terms of unit revenues. This does not seem unreasonable because labor costs constitute more than half of each industry's total operating costs, although the proportion could conceivably differ by commodity. For railroads, the adjusted freight ton-mile measure is combined with a measure of revenue passenger-miles to obtain the total industry output index.

For air transportation and trucking, employment is the only available measure of labor input. Thus, the productivity measures for these two industries should be interpreted with caution, for if changes occur in the average workweek, the trends in productivity would not show the true relationship between output and labor time expended on the output.

The transportation industries for which BLS publishes productivity measures all are regulated to some degree by the Federal Government. Recent efforts to reduce the paperwork burden, coupled with the effects of deregulation, have acted to eliminate some of the operating statistics previously published. As a result, some productivity measures have had to be extended on the basis of more limited information. The outlook for expanding the data base, at least in the near future, is not faverable. However, BLS is cooperating with other government agencies to ensure that adequate statistics for transportation industries remain available.

Communications. The BLS productivity measure for telephone communications covers about four-fifths of the employment in the communications sector. The output index is derived from revenues of all telephone companies reporting to the Federal Communications Commission. The revenues are stratified by major source—local, toll, or miscellaneous—and deflated by specially prepared price indexes for these different services. The labor hours data are based on the Bureau's establishment payroll survey.

At one time, BLS published a productivity measure, the numerator of which was derived from the number of local and long-distance telephone calls, aggregated on the basis of revenue weights. This measure was discontinued in the mid-1950's because of concern that the labor input measure was not consistent with the output measure. For example, private line services, such as leased telephone lines, radio and TV transmission, teletype, and so forth, were reflected in employee hours but not in the output measure as defined. The same was true for calls between stations transmitted through private switchboards and directory services.

A different type of productivity index for the industry was initiated in 1973, with data back to 1951. The numerator of this measure was derived from annual revenue data stratified by major services and deflated, until last year, by price indexes furnished by American Telephone and Telegraph Co. Beginning in 1982, the BLS producer price index for telephone communications will be used to deflate the revenue data, and productivity indexes published for the industry since 1972 will be revised in accordance with the new procedure.

The BLS deflated revenue measure of the output of the telephone communications industry is fairly comprehensive. It includes revenues from private line services, which have grown in importance over the years, as well as those arising from the maintenance of private switchboards by telephone carriers. It also accounts for TV, radio, and computer data transmission by telephone industry facilities, and for directory services. However, certain measurement problems remain unresolved, including the unsatisfactory treatment of differences in intensity of the use of telephone equipment by customers. Intensity of use differences occur when revenue does not vary in proportion to the number of calls made because of flat charges, as in the case of local telephone service or WATS lines. Implicitly, the BLS output measure assumes that the maximum permissible usage takes place under any flat charge system used in the industry.

Business and personal services. In the area of business and personal services, which includes not only business, personal, and repair services, but also education, social services, and political organizations, BLS currently publishes only two measures of productivity, one for hotels and motels, and the other for laundry and dry cleaning services. These measures cover 13 percent of the total employment in the sector.

Because physical quantity information is not available for these two industries, output measures are developed using price-deflated value techniques. The techniques are similar to those described earlier, in that both revenues and employee-hour weights are used to aggregate the output indicators into a total industry output index.

On the input side, the hours of all persons are used as the measure of labor time. As in the trade sector, partners, proprietors, and unpaid family workers make up a significant portion of the work force. Currently, this group accounts for about 15 percent of all persons employed in laundries and 20 percent of the workers in hotels and motels.

BLS efforts to expand coverage in the business and personal service area have been hampered by two major problems. First, because many business service categories are quite broad, it is impossible to account adequately for changes in the mix of their component services. For example, we cannot publish a productivity index for automotive repair shops because there are almost no data available on the types of repairs that are made. The second problem is that not enough services are covered by the Consumer Price Index and, consequently, the deflated value of the output of many uncovered areas would have to be imputed.

Finance. In the finance area, BLS is developing a banking measure in terms of the three major services commercial banks render their customers—deposits, loans, and trust services. While banks also provide non-fund-using services, such as safe deposit and customer payroll accounting, lack of adequate data preclude deriving a measure for them. However, because the proportion of employees engaged in such services is very small, the overall output measure is little affected by the omission.

There has been much controversy over the years as to the appropriate measure of the output of banking. Some analysts have advocated a "liquidity" approach, others, a "transactions" approach. In the former, the banks are viewed as holders of money, and their output is equivalent to the net interest they receive on the volume of deposits held. This interest is the income depositors are willing to forgo to maintain deposits rather than investing directly in assets less readily converted to cash, that is, the value to customers of the liquidity they enjoy from bank services. This approach can be extended to all types of savings accounts, on the principle that the forgone net interest is the value of the bank's services.

The other approach views banking output as a series of transactions; the volume of the bank's output is proportional to the volumes of the transactions handled. BLS has adopted this second approach for its productivity measure.

Accordingly, the final output of banks is defined as an array of depository, lending, and fiduciary services. Estimates of the number of transactions for each of the three service functions must be derived. Because no direct count of the number of transactions is available in many instances, estimates are made from data on the total value of transactions and surveys of average transaction amounts.

Deposit activity is measured in terms of the number of checks transacted and the number of time and savings deposits and withdrawals. (An electronic funds transfer is treated as a transaction on par with one involving payment by check.) The data for demand deposit activities are from Federal Reserve counts and official benchmark surveys. For time and savings deposit activity, the output measure is based on data published by the Federal Deposit Insurance Corporation and on the Functional Cost Analysis conducted annually by the Federal Reserve.

Lending services provided by banks are also measured in terms of units. As in the case of deposit and trust activity, BLS does not use banks' financial data to arrive at the component output measures. Use of such data would be highly misleading even if appropriate deflators could be found. For example, an increase in the aggregate deflated value of loans might simply reflect the making of a few large loans; similarly, a decrease might indicate the repayment of a few large loans, even as the number of small loans increased.

Twelve types of loan output are measured, for the most part using data generated by the Federal Reserve and the Department of Housing and Urban Development. Included in the loan output measure are comm
cial and residential mortgage loans; consumer lo
single-payment loans; credit card loans, and comme
and "other" loans. The number of loans can usuall
derived by dividing the dollar value of total loans
given category by the average face value of a loan.
the category of commercial loans, the actual numbe
loans extended has been available since the mid-197

An experimental output measure for the trust de
ment services of commercial banks is derived from
trend in the number of accounts. Trust accounts
stratified into five major categories, including be
trusts, personal trusts, and estates.

After output estimates are developed for deposi
loan, and fiduciary segments, they are aggregated t
industry level using employment weights.

SOME OF THE MAJOR PROBLEMS in developing l
productivity measures in the service activities and
BLS has tried to meet some of these problems have
highlighted above. Considerable work in this very
portant area has been conducted and the outlook
improvements in certain subareas is optimistic. Fo
ample, as price measures are improved and h
worked data become available, and as work in the
of government productivity measurement progre
BLS will be able to provide a better picture of wh
happening to productivity in more activities withi
sector. Additional measures in communications, fin
insurance, and real estate, and business and pers
services can and will be developed, and indexes
wholesale trade are very possible. However, there
severe conceptual as well as data problems in meas
productivity in such industries as education and s
services and in the important field of medical serv
and progress in these areas is expected to be m
slower.

ment, BLS is exploring the possibility of making adjustmen
changes in work force composition.

Changing the treatment of shelter costs for homeowners in the CPI

In 1983, the treatment of housing in the official Consumer Price Index for All Urban Consumers will change to reflect only the cost of shelter services of owner-occupied housing

ROBERT GILLINGHAM AND WALTER LANE

In late 1981, Commissioner of Labor Statistics Janet L. Norwood announced plans to change the procedures used to compile the homeownership component of the Consumer Price Index (CPI). Although the particular procedures used in compiling the CPI might seem dry and technical and of little general interest, such is not the case with respect to the homeownership component. The treatment of owner-occupied housing in the CPI has been one of the most widely discussed issues in economic statistics in recent years. The interest in this component stems from its substantial weight in the CPI and the sensitivity of the overall index—our most widely publicized measure of inflation—to the particular procedures used.

Currently, the homeownership component is based on house prices, mortgage interest rates, property taxes and insurance, and maintenance costs. This treatment captures elements of both the service flow and asset investment aspects of housing expenditures. The Bureau first raised questions about this component 10 years ago and, since then, has encouraged public review of alternative approaches. For some time, the Bureau staff has supported a change in favor of a treatment which would focus solely on the cost of the shelter services of owner-occupied housing, thus abstracting from investment aspects. The Commissioner believes that the increased general understanding of the issues surrounding this component, along with the growing problems inherent in continuing the current procedure, make a change imperative. This paper summarizes the proposed modifications and the reasons why an immediate decision to make them was necessary,[1] describes the current treatment of homeownership to provide an understanding of the flaws in the current approach,[2] explains why the proposed rental equivalence approach is the best alternative for improving the index, and outlines the technical procedures which the Bureau is currently implementing to ensure an adequate rental equivalence index.

Why the CPI must be changed

As noted, the current approach to homeownership is based on, *inter alia*, house prices and mortgage interest rates. In announcing the changes for the CPI homeownership component, the Commissioner cited several serious difficulties in obtaining reliable data on these components to continue the current approach. First, important changes have occurred in financial markets which are not reflected in the CPI. Funds available for long-term mortgage commitments have declined sharply. New types of mortgage instruments involving variable rates, shorter financing terms, and other special arrangements have developed so that the standard,

---

Robert Gillingham is chief of the Division of Price and Index Number Research and Walter Lane is chief of the Housing Section of that division, Office of Prices and Living Conditions, Bureau of Labor Statistics. An earlier version of this paper appeared in the December 1981 issue of the Office of Management and Budget's *Statistical Reporter*.

long-term, fixed rate mortgage used in the CPI is becoming increasingly unrepresentative of the mortgage market. In fact, some of the new instruments have characteristics, such as variable rates and principal amounts, which make it impossible to use them in computing the CPI which assumes a long-term mortgage at fixed interest rates. Furthermore, because of high interest rates and difficulties faced by home buyers in securing bank mortgages, many owners who wish to sell their homes are facilitating sales by providing financing to buyers at below bank rates. These financing arrangements are not reflected in the CPI. The house prices used in the CPI are obtained from the Federal Housing Administration (FHA) and pertain to sales financed with FHA-insured mortgages. This data base represents a small and specialized segment of the housing market and presents BLS with increasingly serious estimation problems.

In addition to problems of data adequacy, impetus to change the homeownership component stems from an important new use of the index. The Economic Recovery Tax Act of 1981 (Public Law 97–34) requires use of the CPI for All Urban Consumers (CPI-U) for escalation of income tax brackets and the personal exemption amount. The law requires announcement of the new tax brackets in December 1984 based on CPI-U data for the prior 2 years. This is a major new use of the index which will have a broad effect on total Federal Government revenues, and this new use underscores the importance of action to ensure that the CPI reflects the consumption cost experience of consumers to the fullest extent possible.

Another reason to immediately initiate the proposed change is the increasing public awareness of the issues surrounding the measurement of homeownership costs in the CPI. A growing number of concerned parties feel that this component is seriously flawed and that changes must be made in order to maintain public confidence in the index. The specific changes to be made are detailed in exhibit 1. The essence of the decision is to change the homeownership component of the CPI from its current form, which includes both investment and consumption aspects, to a flow of services approach, which focuses only on the consumption of shelter services, on the principle that the index should focus only on current consumption.

Current treatment

In its current form in the index, homeownership has five parts, or elements. Each has its own weight and procedure to estimate monthly price change. The appropriateness of these methods can only be judged in terms of underlying conceptual framework for CPI homeowner costs. Unfortunately, the current treatment of homeownership has no clear conceptual rationale, so the particular procedures used are largely definitional and cannot be justified by resorting to any broader conceptual framework. It is not surprising, then, that much of the debate over homeownership has focused on them.

Exhibit 1. Dates of change in the Consumer Price Index

Date	Action
January 1982	Publication of CPI for December 1981 • increased prominence for experimental rental equivalence measure (CPI-U-X1) in the text of CPI press release
1982	Work on enhancement of CPI-U-X1
February 1983	Publication of CPI for January 1983 • first publication of CPI-U with rental equivalence homeownership • last publication of CPI experimental measures
July 1983	Publication of CPI for June 1983 • last publication of overlap CPI-U with current homeownership methods
1984	Publication of rental equivalence homeownership with expanded rent sample and improved computation methods
February 1985	Publication of CPI for January 1985 • first publication of CPI for Urban Wage Earners and Clerical Workers (CPI-W) with rental equivalence homeownership
July 1985	Publication of CPI for June 1985 • last publication of overlap CPI-W with current homeownership method

Weights. The weights reflect consumption patterns reported in the 1972–73 Consumer Expenditure Survey, which forms the basis for the overall weighting scheme of the CPI. (The relative importance of the items as of December 1980 is given in table 1.) The weight for home purchase is the purchase price for homes bought in the survey year, less the sales price for homes sold, plus transactions costs for these purchases and sales. Thus, consideration is limited to those consumers who purchased or sold homes during the survey period. To reduce the sampling error, data from a longer period (1968–73), annualized and adjusted for the price increase which took place over the period, were used to compute this weight. Use of these procedures resulted in a home purchase weight which is quite large.

Like home purchase, the mortgage interest concept is limited to mortgages obtained in the survey period. The mortgages must be for the purchase of homes, and only mortgages initiated at the time of house purchase are included in the weight. The weight for "contracted mortgage interest cost" is the amount of interest that survey period borrowers promise to pay during the first half of the term of their mortgage loans. It is called contracted mortgage interest cost because it includes future payments. With long mortgages, homeowners will not, in general, hold their mortgages for the full term. The choice of half the term for the specification of this weight was based on procedures established during the 1964 CPI revision.

The weight derivations for the other homeownership elements follow more conventional CPI methods. They depend only on expenditures actually made in the survey year, and refer to expenses incurred by all survey year homeowners—not just home buyers.

Measuring house price changes. The estimate of the monthly change in house prices is one of the most difficult tasks entailed in the CPI. This estimate moves the weight for home purchase and, with a mortgage interest rate index, is also used in estimating the mortgage interest cost index. It is not feasible to follow, over time, the prices of a fixed sample of houses—a practice which would be analogous to that used to track price change on most consumer goods and services—because individual houses change hands only infrequently. So, a new selection of recently sold homes must be used each month. To obtain an estimate for the change in house prices from last month to this month, the average price of this month's set of homes must be compared—after adjustment for quality difference—to the average price for last month's set.

The primary difficulty in pursuing this approach is finding a source of data on recent house sales, with both price and quality information, that are (1) available promptly and (2) inclusive of the various types of houses and housing areas. In the current CPI, the data are for house sales on which financing is insured by the Federal Housing Administration. These data fall far short of the ideal. Processing delays often mean that several months elapse between the time a house sale occurs and the time it is used in the CPI. For some geographic areas, especially those in the Northeast, the number of FHA transactions is very small. In addition, the FHA mortgage ceiling virtually eliminates higher priced homes from consideration. The impact of the ceiling—and especially changes in the ceiling—may be quite substantial, possibly resulting in a downward bias in the house price indexes used in the CPI.[3]

The other important difficulty in estimating house price change is the development of good quality adjustment procedures, required before a valid comparison between two different samples can be made. Quality adjustment is currently accomplished by sorting the observations on FHA sales into 600 mutually exclusive cells. The cells were generated from the cross classification of the 40 CPI geographic areas, 5 age ranges, and 3 size groups. The estimate of change in house prices is computed from the cells. First, the average of the prices per square foot is obtained for each cell. Second, the change is computed for each cell from the average price per square foot of the previous month. Finally, the average of the change is taken over the cells with weights that reflect the base period importance of each cell.[4]

Mortgage interest and other cost changes. Changes in mortgage interest costs are determined from the combination of (1) an estimate of changes in mortgage interest rates and (2) the estimate of the changes in house prices. Thus, the mortgage interest cost element of the CPI shows the effect of changing interest rates, with other loan features held constant, and changing house values, with house quality held constant. Put another way, this element shows the change in the amount required to finance a given house in the face of changes in both the interest rate and the price of the house.

The rate change is estimated using quality control cells similar to those used for house prices. For conventional loans, the cells result from the cross classification of the 40 CPI geographic areas, 3 downpayment classes, and 2 classes to distinguish between mortgages on new and existing houses. The source data for conventional loans are provided by the Federal Home Loan Bank Board. They consist of all mortgages closed during the first 5 business days each month by a sample of savings and loans and other lenders. There is currently a 1-month lag before the data are used in the CPI. In addition, there are cells for FHA and VA ceiling rates; these have 13.5 percent of the mortgage weight.

Price changes for the other homeownership elements are estimated with the standard CPI technique of following the prices of a fixed set of selected items over time. The property taxes on a sample of homes are tracked from year to year, after removing the effect of capital changes and exemption changes which are not the result of new tax rules. Price change for property insurance is

Table 1. Relative importance of index components of the official (CPI-U) and experimental (CPI-U-X1) measures, December 1980

Component	Relative importance	
	CPI-U	CPI-U-X1
All items	100.000	100.00
Food and beverages	18.309	21.264
Housing	45.519	36.720
Shelter	31.650	20.613
Rent, residential	5.120	5.946
Other rental costs	.714	.830
Homeownership	25.816	13.937
Fuel and other utilities	6.560	7.604
Household furnishings and operation	7.319	8.503
Apparel and upkeep	4.854	5.639
Transportation	18.955	22.020
Medical care	4.717	3.476
Entertainment	3.647	4.237
Other goods and services	3.999	4.643

estimated by following the price of a specified amount of homeowners or fire and extended coverage insurance, with annual inflation adjustments to any dollar values used in the specifications. For maintenance and repair expenses, a specified set of commodities and services are priced in retail outlets by CPI field representatives.

The rental equivalence approach

The current treatment of homeownership in the CPI has some very ad hoc aspects: there is no recognition of the distinction between investment and consumption, nor is there any clearly identified underlying conceptual structure. This is not the case for the rental equivalence approach. The following summarizes the conceptual arguments for this approach and outlines the operational steps which will be taken to ensure that the approach is effectively implemented.[5]

Conceptual framework. The overall conceptual framework for the Consumer Price Index was presented by Robert Gillingham in 1974. To summarize, we assume that the consumer's welfare is determined by the flow of consumption services received, where the services can be (1) directly provided, (2) obtained coincidentally with the consumption of a nondurable good (in which case the distinction between a good and a service is unnecessary), or (3) obtained from the use of a durable good owned by the consumer. In each case, satisfaction is derived from the act of consumption; ownership of a source of consumption services—a durable good—produces no additional satisfaction. In other words, the purchase of a durable good is an "investment," designed to provide consumption services over a future time span.

Within this framework, we want the CPI to measure the cost over time of the market basket of services *consumed* in the base period. For the services provided by directly-purchased services and nondurable goods, this implies observing market prices and transaction levels in the base period, as well as the subsequent time path of market prices. However, for the services provided by durable goods owned by consumers, the implicit price of the services must be estimated, because market transactions do not take place each time the service is consumed.

Within this framework, the problem is basically one of estimation. This problem is not serious for many durable goods because aggregate service flows and aggregate purchase flows are closely related, and asset price movements are closely related to service price movements. Thus, standard techniques can be used. For housing, however, this pattern does not typically hold, and alternative procedures must be developed. To analyze this problem for housing, we will start by defining the user cost of housing in the simplest case—in a world of certainty without taxes, and with perfectly competitive markets—and proceed to outline the complications which arise when these assumptions are dropped.

In a world with perfect rental and resale markets and no uncertainty, the user cost of a house in a given period can be shown to be the following:

$$C_t = r_t P_t - A_t + Z_t \tag{1}$$

where r is the (single) rate of interest in period t, P is the average price of the house in period t, A is equal to the change in the average price over the period, and Z represents all other cost components. In other words, the user cost is defined as the opportunity cost of holding the house, $r \cdot P + Z$, less the increase in the house's value. In equilibrium, the rental price of the house, R, will be equal to the user cost and, because we have assumed frictions away, the rent received by a landlord will equal the rent paid by a tenant. Thus, in a perfect world the following obtains

$$R_t^L = C_t = R_t^T \tag{2}$$

where the superscripts L and T denote landlord and tenant.

Under the conditions we have assumed, measurement of the value of the flow of shelter services from a house becomes a trivial matter. It can be measured with information from either rental or resale and money markets and it does not matter whether the information refers to buyers' or sellers' prices. Problems arise, however, when we attempt to measure the cost of shelter for homeowners in a more complicated setting, in which the exact form of the user cost function is more difficult to define and the equalities above need not hold.

To lay out this problem more clearly, we will drop the assumption of perfect certainty, thereby allowing for a structure of differing asset yields. We will also relax the assumption of perfect markets to allow for the possibility that the rent received by a homeowner may be less than the rent paid by a tenant, the difference representing, for instance, the value of a management function. Although we no longer assume perfect rental markets, we do assume that there is some price at which each homeowner can rent shelter services equivalent to those provided by his own home, and some strictly positive price at which another consumer would be willing to rent his house. Under these conditions, the user cost measure can be redefined as

$$C_t = r_{et} E_t + r_{mt} M_t - A_t + Z_t \tag{3}$$

where M and E are mortgage and equity amounts which sum to the average price of housing (P), r_m is the mortgage interest rate, and r_e is the opportunity cost of equity capital.[6]

The relationship between user cost, defined in this manner, and the alternative rent measures defined above is now ambiguous, and depends critically on the manner in which the opportunity cost of equity capital is defined. Certainly, the rent paid by a tenant must be greater than or equal to that received by a landlord, but depending on the manner in which one chooses to define and estimate the opportunity cost of equity capital, the relationship between each of the rent measures and user cost is uncertain.

The variables included in the redefined user cost function are all conceptually and operationally straightforward with one crucial exception—the opportunity cost of equity capital. Unfortunately, estimates of user cost are also sensitive to alternative definitions of this variable. In 1980, Gillingham presented several somewhat "natural" alternatives for defining the opportunity cost of equity capital.[7] In 1972, he had suggested that r_e be estimated as an internal rate of return defined by the identity

$$(4) \qquad R^L_t + A_t \equiv r_{et}E_t + r_{mt}M_t + Z_t$$

where R^L_t is an estimate of the market rental which an owner could receive for his house.[8] Alternatively, one might argue that the appropriate internal rate of return be defined by substituting R^T in equation (4). In either case, the resulting estimate of user cost, which we will call C_1, reduces to an implicit rent, and the following relationship holds:

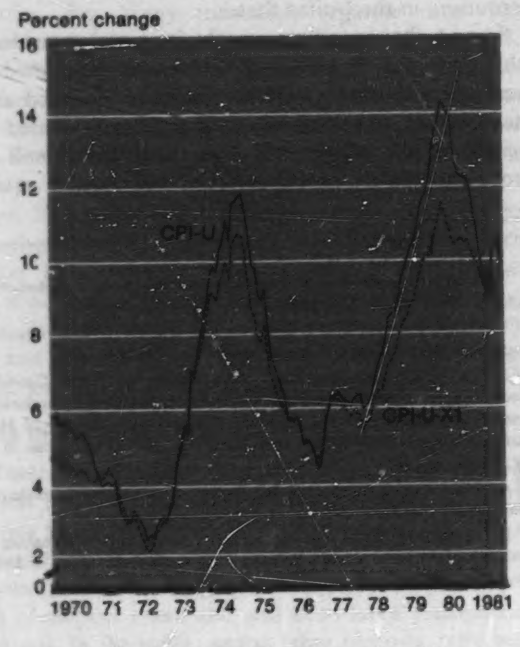
$$(5) \qquad R^L_t \leq C_{1t} \leq R^T_t$$

The suggestion to use an internal rate of return on housing to estimate user cost is based on the assumption that this rate best describes the alternative rate of return an owner/investor could receive on another investment with similar liquidity and risk characteristics.

That is, the household's user cost of owner-occupied housing or cost of *consuming* the flow of services from its housing unit must be at least as great as the income which the household could receive by renting the unit to someone else. This cost is independent of the capital gains achievable from holding housing assets, except insofar as such gains are reflected in rent levels. Each household determines its housing stock based on decisions regarding the expected rates of return on housing equity and other assets with varying characteristics. This determination is separate, however, from the decision as to the rate of consumption of housing services. Such factors as the rate of change in house prices determine the rate of return on equity, but *ex post* capital gains do not affect the user cost. In the same way, defining r_e other than as the internal rate of return has the effect of incorrectly including in C some element of the investment return on housing investments. This result implies that rental equivalence measures are a necessary input into the development of acceptable user cost measures.

Empirical implementation. The foregoing discussion emphasizes the importance of explicit or implicit rental market information in developing conceptually sound user cost measures. It has been demonstrated that estimated user cost functions are subject to extreme volatility and that direct use of rental market information is a far more promising approach.[9] The basic question then becomes the appropriate design of a rental equivalence estimation procedure.[10] Over the past several years, the Bureau has produced an experimental rental equivalence index (CPI-U-X1) which simply uses the rent index to move a rental equivalence weight derived from the 1972–73 Consumer Expenditure Survey. Relative importances for this index are shown in table 1 and the rela-

Chart 1. Changes in the Consumer Price Index for All Urban Consumers, official (CPI-U) and experimental rental equivalence (CPI-U-X1) measures, 1970-81



NOTE: Percent changes are calculated using 12 months of unadjusted data.

tive movements of this index and the official index are displayed in chart 1. Although CPI-U-X1 gives a rough idea of how a rental equivalence index would move, the Bureau believes several procedural improvements are required before an official rental equivalence index is introduced. Following are the steps currently underway to improve the method of calculating the rental equivalence measure now used in the CPI-U-X1. This work will be completed in the latter part of 1982 and will be ready for introduction into the CPI-U with data for January 1983. (See exhibit 1.)

Specifically, three limitations of the current rental equivalence measure will be addressed. First, the sample of rental units now used will be reweighted so that it will represent owner-occupied housing units instead of renter-occupied units. The current sample of rental units was selected, with a probability-based technique, from the renter-occupied units in selected neighborhoods in each CPI pricing area. The rent survey neighborhoods were selected using, among other stratification variables, the percent of the neighborhood that was owner-occupied. By taking advantage of this element of the design of the rent survey, new weights can be assigned to the housing units in the sample so that they will represent the owner-occupied housing units in their neighborhoods, CPI areas, and, ultimately, all urban places in the United States. The reweighted rent sample can then be viewed as representing—under the rental equivalence concept—homeowner costs for all urban consumers in the United States.

Second, the expenditure weight for rental equivalence, which for the experimental index was calculated by means of a short-cut method, will be recalculated using the complex statistical estimating procedure used for weights in the official CPI. This enhancement will improve the quality of the national CPI's rental equivalence weight, and will provide weights for computation of local area CPI using the rental equivalence approach.

Finally, the data processing system which produces the CPI each month will be expanded to accommodate the calculation of a CPI-U, with complete item and geographic detail, which employs the rental equivalence approach.

Subject to resource availability, longer range plans for improving the rental equivalence measure include an augmentation of the sample of rental units. This new sampling will be concentrated in areas where the housing is predominantly owner-occupied in order to increase the proportion of rental units that have characteristics similar to owner-occupied units. In addition, improvements in the statistical estimating techniques for rental equivalence will also be developed.

THE DECISION TO CHANGE to a flow-of-services approach in measuring shelter costs for homeowners implies a major conceptual change for this component of the CPI. We believe the current approach is severely lacking in conceptual rationale, and that the proposed changes will be a great improvement. Much of the controversy over the change, however, has centered around the empirical question of which index will increase more rapidly over the next several years. As shown in chart 1, the rental equivalence index increased less rapidly over the past decade. However, this period has been marked by substantial activity in housing markets and widely fluctuating mortgage interest rates. It would be extremely difficult to predict relative future movements and, thus, the decision to change the index should be based on conceptual and operational adequacy, a subject on which we do have information, rather than on predictions of future movements in the indexes, a subject on which our information is extremely uncertain. ☐

[10] *Ibid.* Gillingham produces experimental rental equivalence indexes using a very different set of procedures unsuited for use in the CPI. The results, however, give no evidence that a reasonable rental equivalence measure would be excessively difficult to produce.

Labor turnover in manufacturing: the survey in retrospect

Discontinued Federal-State series shows level of hires, quits, and other job changes has remained relatively stable except for cyclical variations; analytical limitations include coverage of industries that have become less representative of the economy

CAROL M. UTTER

With the compilation of data for December 1981, the Bureau of Labor Statistics has ended its survey of labor turnover, predominantly in manufacturing. The monthly survey, a key economic indicator, was discontinued because of severe budgetary cutbacks.

The labor turnover survey was initiated in 1926 by the Metropolitan Life Insurance Co. to provide personnel managers with a national benchmark of turnover rates in manufacturing plants. In 1929, the company turned the project over to BLS for further development, and BLS had been collecting data monthly since 1930. In the first 10 years, the Bureau expanded the original sample of 175 large establishments, which employed 25 percent of all manufacturing workers. In the meantime, a number of State employment security agencies affiliated with the U.S. Employment Service of the Department of Labor were collecting labor turnover information for use in local job market analysis and as a guide for the operations of the State employment services. Cooperative arrangements between these agencies and the Bureau of Labor Statistics for the joint collection of labor turnover data began with an agreement with Connecticut in 1954.

By 1964, the cooperative program had been extended to cover all 50 States and the District of Columbia, and the total sample comprised 40,000 reporting establishments in manufacturing and mining. By the late 1960's, these agencies published about 8,000 labor turnover series of States and Standard Metropolitan Statistical Areas, while national rates were published for 221 industries. For many industries, separate rates were published for men and women between 1958 and 1968.

In 1969, the survey was expanded to include the collection of information on job openings. During the next 4 years, information on labor turnover and job openings was collected for all manufacturing and mining industries as well as for nonmanufacturing industries in about 20 selected standard metropolitan areas. The job openings portion of the survey was discontinued at the end of 1973 and with it the collection of turnover data for most nonmanufacturing industries.[1] Monthly turnover information continued to be collected for all mining and manufacturing industries, entailing 260 national series and nearly 11,000 State and area series.

Uses of the data

These statistics have been used primarily for economic and labor market analysis and for research. In the private sector, employers have used the data on quits as a yardstick against which to measure the performance of their plants, with low quit rates considered an indication of efficient operations and good labor management relations. In the public sector, labor turnover rates were also widely used by State employment services to plan and appraise their operations. For example, the State employment security agencies compared the number of

---

Carol M. Utter is a statistician in the Office of Employment Structures and Trends, Bureau of Labor Statistics.

employees placed through their services with the total number of new hires reported by employers within the labor market served by a particular local employment service office. Thus, the number of job placements by each local office could be measured relative to the potential for placement in the local job market.

Over the years, the major use of the labor turnover rates was as an economic indicator. The layoff rate signaled changes in the economy several months before business turning points, particularly the starts of downturns. The Bureau of Economic Analysis included the layoff rate as one of the 12 components of its composite Index of Economic Leading Indicators. (See table 1.)

Analysts have also found the quit rate to be a particularly useful representation of the decision of individual employees regarding their perceptions of the availability of other job opportunities.

From 1950 through 1979, accessions (new hires, recalls, and transfers) ranged decennially between 4.5 percent and 4.1 percent, while separations (mainly quits and layoffs) ran about 4.3 percent. The average rate of new hires for each decade stood at 2.9 percent per month, while the average rate of quits was about 2 percent. For 1980 and 1981, turnover slowed as business conditions worsened. (See table 2.)

In general, one notes little evidence of increased job hopping or any particular change in employers' use of layoffs to adjust their work force to slackening business conditions. Of course, the manufacturing sector has not grown in employment during the postwar period and its share of the Nation's nonfarm jobs dropped from 34 percent in 1950 to 22 percent in 1981. Therefore, accessions have not exceeded separations as would have been the situation if labor turnover data for the total economy or the fast growing service sectors were included.

The foregoing is intended merely as a brief description of the behavior of the series. Many detailed analyses of the series have been published, including the *Monthly Labor Review* article, "Quits in manufacturing: a study of their causes."[2]

Table 1. Layoff rate in relation to the business cycle, November 1948 to July 1981

Cyclical phase	Layoff low	Months leading	Layoff rate[2]
Contraction[1]			
Nov. 1948	Dec. 1947	11	1.0
July 1953	Nov. 1952	8	.8
Aug. 1957	Nov. 1955	21	1.3
Apr. 1960	May 1959	11	1.7
Dec. 1969	Apr. 1969	8	1.1
Nov. 1973	Oct. 1973	1	.8
Jan. 1980	Mar. 1979	10	.9
July 1981	July 1981	0	1.0
Expansion[1]	Layoff peak	Months leading	Layoff rate[2]
Oct. 1949	May 1949	5	3.4
May 1954	Jan. 1954	4	2.9
Apr. 1958	Mar. 1958	1	3.5
Feb. 1961	Feb. 1961	0	3.0
Nov. 1970	Oct. 1970	1	2.2
Mar. 1975	Feb. 1975	1	3.0
July 1980	May 1980	2	3.2

Table 2. Average monthly labor turnover rates in manufacturing, 1930–81

Period	Total accessions	New hires	Total separations	Quits	Layoffs
1930–39	4.8	—	4.7	1.2	3.4
1940–49	6.9	—	6.6	4.1	1.7
1950–59	4.5	2.9	4.4	2.0	1.8
1960–69	4.3	2.9	4.3	1.9	1.7
1970–79	4.1	2.9	4.3	2.0	1.3
1980–81	3.4	2.1	3.8	1.4	1.6

Limitations of the series

One of the major shortcomings of the terminated program has been its limited scope. The industry coverage—limited to manufacturing, mining, and telephone communications—has become less representative of overall economic behavior. In the last 30 years, while the number of full- and part-time workers on nonagricultural payrolls has doubled from 45 million to more than 90 million, only 1 out of every 9 jobs added went to manufacturing industries. Thus, the usefulness of the statistics in measuring the job mobility of the entire work force has diminished. The lack of data by occupation has also been considered a problem by many users and limited the usefulness of the series to aid in guiding development of occupational training programs.

There has also been an increasing concern over the low level of labor turnover recorded in the series.

In the mid-1970's, the Employment and Training Administration (ETA) began to investigate alternate sources of labor turnover information relating to all industries. Funded by ETA, several State employment security agencies derived labor turnover from administrative records maintained for the unemployment insurance system.[3]

The significantly higher new-hire rates derived from this source than those produced by the BLS survey for manufacturing industries pointed to problems in the design of the labor turnover sample. It was essentially a "size cutoff" sample directed at establishments with 50 or more employees. The new-hire rates of the few small establishments in the BLS sample were 2 or 3 times higher than corresponding rates of larger establishments. In addition, many of the larger establishments in the sample had cooperated in the program for a long time, were well established, and appeared to have less turnover than large establishments not in the sample. There was also a regional bias in the sample, with some of the fast growing States, particularly California, being underrepresented. The Bureau had been aware of these problems for some time, but funds had not been available to make the necessary improvements in the sample design and in the estimating methodology.

However, several studies have shown that the degree of bias in the survey results was considerably smaller for total separations. On this basis, the quit and layoff data retained validity as an economic indicator.

Alternate sources

Although the labor turnover survey was the only source for current statistics by detailed industry categories for the manufacturing sector, there are a number of other sources that provide information which users may substitute for the BLS survey. The labor turnover rates derived through the operations of State unemployment insurance systems have the potential of providing quarterly rates of total separations, total accessions, and new hires by industry for previous quarters. These turnover rates are computed by comparing the social security numbers of employees working for a given employer in a given quarter, as reported on the employer's quarterly unemployment insurance tax report, with the social security numbers reported by the same employer in prior quarters. Unfortunately, this methodology cannot distinguish between the types of separations, such as quits and layoffs.

At present, 12 States do not have unemployment insurance systems which require regular reporting of quarterly wages for each employee identified by social security numbers, a requisite for using this methodology. Only 21 States are currently producing labor turnover rates with this methodology, and seven more are in the developmental stage of producing the rates.

As a one-time project, the methodology was applied to a special tabulation of a 1-percent sample of quarterly social security records made available by the Social Security Administration. This study provided, for the first time, information about the volume of accessions, new hires, and separations in all industries and all States for the second quarter of 1974.[4] Because of changes in the filing requirements for employer reports for social security taxes, this source is not available for years after 1976.

The best alternate source for current information on layoffs is the ETA's *Unemployment Insurance Weekly Claims Report.* Initial claims derived from that source will be used by the Bureau of Economic Analysis in place of the layoff rate in manufacturing as one of the 12 components in calculating the Index of Leading Economic Indicators. The Current Population Survey is another source of statistics on labor turnover. Information on unemployed persons on layoff is collected each month, and data are published in *Employment and Earnings* by various characteristics, such as age, sex, race, and duration of unemployment. Unpublished data are available by other characteristics, including industry of last job, although the industry detail is limited. From time to time, the survey is also used to collect data on job tenure and mobility.

The Office of Personnel Management calculates labor turnover rates for Federal employees from its Central Personnel Data file. These data are published monthly for all Federal agencies. Separate rates are available for total accessions, total separations, new hires, transfers, quits, and all other separations.

There are several private organizations that collect and disseminate labor turnover information. The most important of these sources is the Bureau of National Affairs. Since 1974, this organization has been collecting labor turnover information from about 600 large companies in all industries. The data are collected quarterly and are published in a bulletin shortly thereafter.[5] The definitions and estimating methodology used by this organization are comparable to those that have been used by BLS. The limited sample size does not allow the production of any industry detail. The Administrative Management Society has been collecting annual data on separations of office employees approximately every other year since 1969. The results of this survey, derived from about 2,000 reporting companies in a wide spectrum of industries, are published in the Society's *Management World* journal.[6] The separations data are restricted to office employees only and do not include temporary layoffs and certain leaves of absence.

Historical data on the BLS national labor turnover series will be maintained in the BLS data base and will be provided to users who request all or part of the file. The data can be provided as listings or on tape. The Bureau does not maintain a data base for any of the State and area series, but some of the State agencies which had cooperated in the survey may be able to provide these data to interested users. ☐

Occupational winners and losers: who they were during 1972–80

Job gains occurred in most occupational groupings in which Americans were employed during the 1970's, but close to half of the overall employment increase took place in just 20 of the 235 occupations; and, several job groups lost thousands of workers

CAROL BOYD LEON

Most occupations gained workers in the 1970's. An employment increase of 15.6 million persons during 1972 to 1980 was dispersed among three-fourths of the 235 or so occupational categories in which most persons were employed. However, almost half of this job growth can be attributed to just 20 occupations—including secretaries, cashiers, registered nurses, and cooks. Among occupations declining in size were delivery workers, cleaners and servants in private households, and farmers. (See exhibit 1.)

This article looks at employment changes among the biggest occupational winners and losers of the 1970's. Two sets of criteria were used to choose the winners. An occupation must be one of the top 20 in terms of the number of workers added to the annual average employment level between 1972 and 1980—these increases ranged from more than 200,000 to nearly 1 million; alternately, the job group must have been one of the 20 which grew by 75 percent or more. The majority of occupations which met these tests were in either professional or clerical fields. Four job groups—computer specialists, computer operators, health technologists and technicians, and bank tellers—met both criteria. For all winners, job expansion by industry and by sex is examined.

The 10 biggest losers of 1972–80—that is, occupations which declined by 60,000 workers or more—were generally other than white-collar jobs. (Percentage decrease in employment was not used as a criterion for job losers because only occupations with extremely small numbers of workers in them declined by a large proportion and their absolute loss of workers was small.) Various technological and sociological changes help account for many of the employment decreases, as will be pointed out later.

The Current Population Survey, which is the article's major data source, provides employment information for about 435 detailed occupations. However, this discussion is limited to those which posted a 1980 annual average employment level of 50,000 workers or more. To determine growth during the 1970's, annual averages for 1972 and 1980 are used; the year 1972 was chosen as the base year because earlier data are not available for all occupations on a comparable definitional basis.[1]

Where has the growth occurred?

About half of the 15.6 million increase in employment between 1972 and 1980 took place among two white-collar groups—professional and technical workers rose by 4.2 million and clerical workers registered a gain of 3.9 million. Next highest were managers and administrators with an increase of 2.9 million, service workers (excluding private household workers) with 2.4 million, and craft and kindred workers with 1.7 million.

Carol Boyd Leon is an economist in the Division of Employment and Unemployment Analysis, Bureau of Labor Statistics.

Exhibit 1. Occupations ranked by the size of their absolute employment changes, 1972–80

Largest increases	Largest decreases
Secretaries	Delivery and route workers
Cashiers	Cleaners and servants
Registered nurses	Farm owners and tenant farmers
Cooks	Unpaid family farmworkers
Truckdrivers	Garage workers and gas station attendants
Accountants	Sewers and stitchers
Engineers	Child-care workers
Computer and peripheral machine operators	Textile operatives
Bookkeepers	Telephone operators
Computer specialists	Stenographers

Only small increases were posted among salesworkers, operatives, and nonfarm laborers, while there were declines of about 400,000 each among private household and farmworkers.

Growth rates follow a similar pattern. These measure the increase in employment relative to the initial (1972) employment level of the occupation. As shown below, white-collar groups—in particular, professionals, managers and administrators, and clerical workers—experienced the fastest growth between 1972 and 1980, followed by service workers (excluding private household):

Occupation	*Employment change, in percent*
Total	19.1
White-collar workers	30.0
Professional and technical workers	36.3
Managers and administrators, except farm	35.9
Salesworkers	15.3
Clerical and kindred workers	27.1
Blue-collar workers	7.8
Craft and kindred workers	15.9
Operatives, except transport	0.1
Transport equipment operatives	8.1
Nonfarm laborers	6.9
Service workers	18.2
Private household workers	−27.6
Other service workers	25.1
Farmworkers	−11.9

The only blue-collar occupational group which even came near the average growth rate was craft and kindred jobs. Generally speaking, as the service-producing sector expanded, so did office and service jobs, while slow growth in manufacturing and other goods-producing industries limited the increase in the employment of production workers.

Women accounted for about 65 percent of the employment rise over the period, an amount disproportionate to their 38-percent share of total employment in 1972. Many of the specific occupational winners—including the top five mentioned earlier—were "female-dominated." Women also made up a relatively large share of the job gains in all major occupational groups which experienced growth. More specifically, women accounted for at least half of the increases in employment in each of the major groups except craft and kindred jobs, where 1 of 5 additional workers was female. And even among craftworkers, women composed much of the employment advance compared with their portion of all craft jobs, as they accounted for fewer than 1 of 25 craftworkers in 1972. In two occupational groups, women made up 100 percent of the (limited) job gains, as the number of men employed as nonfarm laborers remained about the same and the number working as operatives except transport declined. Women made up a small part of the drop in farmworkers but virtually all of the decrease among private household workers.

Surge among white-collar groups

The proportion of workers employed in white-collar occupations reached 50 percent for the first time in 1976 and exceeded 52 percent by 1980. The continual climb in the proportion of these jobs can be attributed to three of its four major occupational groups—professional and technical workers, managers and administrators, and clerical workers.

Professional workers. The most growth took place among professional workers; seven specific occupations with increases of 200,000 or more fall under this heading. (See table 1.) The biggest employment gain was among registered nurses, whose job count was boosted by the growing demand for health services throughout the 1970's. (However, demand for services does not necessarily imply a simple one-to-one relationship to job growth in the health or any other industry. Other factors, such as relative wages received by persons in the occupation, the supply of workers with appropriate skills, changes in productivity and technology, and the degree to which other types of workers can satisfy the additional demand may all contribute to determining the magnitude of the employment change.) The health industry boom—caused by the greater availability of medical insurance, a larger and older population, and more public awareness of quality health care, among other factors—led to the job gains for nurses, as well as for dieticians, therapists, health technicians, administrators, and health aides.[2] The number of physicians increased too, but their rate of growth was slower than that of other health workers. The employment advance among registered nurses, which totaled 500,000 during 1972–80, occurred mainly among those in hospitals (350,000) and in medical offices (125,000). Although the number of male nurses more than doubled—they totaled 45,000 by 1980—95 percent of the job gains occurred among women.

The category of health technologists and technicians was among the biggest gainers—both in the size of the job gain and the growth rate of the employed—although they posted an employment increase of only half that of registered nurses. (See tables 1 and 2.) As the demand for skilled persons to operate highly sophisticated diagnostic and therapeutic equipment grew, the employment level of health technologists and technicians advanced by approximately 255,000. More than half of this gain was among hospital workers, particularly those employed as clinical laboratory and radiologic technicians. As one might suspect, substantial increases also occurred among health technicians working in medical offices and other such facilities. A much smaller, but still noteworthy, gain took place in local government, which employed very few health technologists and technicians in the early 1970's compared with 13,000 by 1980. Women accounted for about two-thirds of the total increase among health technologists and technicians, in line with their representation in that occupation.

In another health-related occupation, therapists posted an 85-percent increase (almost 100,000), as the health industry as a whole grew rapidly. The exceptionally fast growth rate among therapists can be partly traced to stronger interest in, and funding for, rehabilitation programs. The representation of women among therapists advanced from about 60 to 75 percent from 1972 to 1980, as the vast majority of new therapists were women.

Table 1. Occupations with the largest absolute increases in employment between 1972 and 1980

[Numbers in thousands]

Occupation	Employed		Employment increases		Rank by size of increase
	1972	1980	Number	Percent	
Total employed	81,702	97,270	15,568	19.1	—

NOTE: Data are annual averages.

While still a relatively small health occupation, the number of dieticians grew swiftly, as their employment total rose from less than 35,000 to 60,000. As about 9 of 10 dieticians are women, virtually all of the job gains were registered among women. Like the other health workers, both therapists and dieticians found most job opportunities in hospitals, nursing homes, and other medical facilities.

The professional group which posted the next largest increase after nurses—about 335,000—was accountants. As business and individuals became more aware of the need for financial management, demand for accountants and accounting firms expanded; in fact, the rate of growth of accountants—a group which includes income tax advisers and others with accounting skills—was about twice that of total employment. About 30 percent of the job gains took place among those in professional services industries, especially the accounting, auditing, and bookkeeping services industry (although accountants working for hospitals and educational services made up part of the increase). An additional 20 percent of the advance occurred among manufacturing industries, with most of that rise being registered in firms which produce durable goods. The remaining 50 percent of the increase was spread among numerous industries, including public administration at all three levels of government, banking and finance, wholesale trade, and insurance and real estate. Although most accountants are men, the female share of the industry rose by 15 percentage points, to about 36 percent, as two-thirds of the additional accountants were women.

Engineers had a substantial employment rise, as their job count moved ahead by 330,000. Close to half of the job growth for engineers was in manufacturing. Next came professional services, and noticeable growth also occurred in business services, public utilities, and public administration (State and local). Industrial, and electrical and electronic engineers experienced the largest job gains, followed by mechanical engineers. These were also the fields in which employment of female engineers expanded the most. Although women made up only 15 percent of the total employment advance of engineers, their 50,000 increase was exceptional, considering there were fewer than 10,000 female engineers in 1972.

Related to the job gains among engineers was a rise of 265,000 among engineering and science technicians. These gains were spread throughout the economy but, like that of engineers, much of their employment increase was in manufacturing. Especially rapid growth in the production and use of electrical and electronic equipment and computer equipment accounted for a sustantial number of new engineering jobs in those manufacturing industries and in the field of telecommunications. Although engineering and science technician jobs traditionally have been filled by men, women accounted for 45 percent of the 1972–80 growth, thereby doubling their representation in the occupational group from 9 to 18 percent.

Well known for its growth is the computer field, as advances in computer technology and usage have generated literally hundreds of thousands of jobs during both the 1960's and 1970's. Among just the professional job categories, computer specialists—mainly programmers and analysts—increased from about 12,000 in 1960[3] to 275,000 in 1972 and to nearly 585,000 by 1980. The number of persons employed as computer programmers came close to doubling during the 1972–80 period, while computer systems analysts were not far from tripling their 1972 level. Both of these occupations were among the 20 fastest-growing, and systems analysts were at the top in terms of percentage growth. Interestingly, it is difficult to pinpoint those industry groups in which most of the employment increase among computer specialists took place, because computers influenced nearly every major industry. As technological advances have made better computer equipment available at more reasonable prices, industries with firms which could not previously afford computers—such as some business services—and industries which grew only slightly during the 1970's—such as several durable goods manufacturing industries—incorporated computers into their operations.[4] Other large increases in the employment of computer specialists occurred in transportation and public utilities, especially telecommunications; finance, insurance, and real estate; nondurable goods manufacturing; public administration; and professional services, particularly educational services. (Employment advances in another computer-related occupation, computer operator, will be discussed later in this article.)

The female share of computer specialist jobs rose from 17 percent in 1972 to 26 percent in 1980, as 1 of 3 additional jobholders was a woman. Women continued to be more likely to be programmers than systems analysts—although female representation among both groups of workers increased substantially.

While lawyers make up one of the top 20 occupations only in terms of the size of their employment increase, both the absolute size of their gain—220,000—and their rate of growth—more than 70 percent—were notable. The demand for lawyers grew rapidly as businesses and individuals called upon them to untangle and interpret laws which are increasing in number and in complexity. About two-thirds of the rise in the employment of lawyers, which includes law clerks and many paralegal workers, took place among the group to which the majority belong—that is, those in private practice, either with law firms or alone. Proportionately speaking, a larger increase was registered among government lawyers, whose number more than doubled between 1972 and 1980 (from 40,000 to 90,000). Nearly a quarter of the job gains for lawyers were in public administration, with increases occurring at Federal, State, and, especially, local levels. Most of the remaining rise in employment—about one-tenth of the total increase of lawyers—was among those employed as house counsel by private firms, and a small increase was noted among law teachers.

Although the practice of law traditionally has been a "man's job"—women accounted for only 4 percent of all lawyers in 1972—1 of 4 lawyers added to the job count during 1972–80 was a woman. By 1980, the fe-

Table 2. Occupations with the largest percentage increase in employment between 1972 and 1980

[Numbers in thousands]

Welfare service aides	34	87	53	155.9	3

NOTE: Date are annual averages.

male proportion of employed lawyers was 13 percent, and this share is expected to continue rising.

Two of the three professional occupations which more than doubled in size fall under the social sciences heading—psychologists and economists. Psychologists are heavily concentrated in just a few industries; accordingly, their 55,000 increase was accounted for almost exclusively by job gains in professional services. Hospitals and medical offices provided opportunities for slightly more than half of the additional psychologists, while other services industries, including educational ones, absorbed most of the remainder. More than half of the increases took place among women, bringing their share of the employment total for psychologists to just over 50 percent.

The industrial distribution of economists is much more diverse, and so their 70,000 rise was spread among many types of businesses. About 30 percent of the advance took place in manufacturing firms, while banks and particularly business services—such as securities and investment companies, economic research firms, and management consulting firms—made up another 30 percent. About 2 of 5 economists added between 1972 and 1980 were women, making their proportion 25 percent.

The third group of professionals which more than doubled in size was composed of authors, including magazine free-lancers, speech writers, and television writers. About three-fourths of all authors in 1980 were self-employed and, accordingly, most of the increase of 40,000 was among self-employed workers. Men and women shared equally in the group's employment gain, and the proportion of women in this occupation was about 43 percent in both 1972 and 1980.

Other fast-growing professional occupations include biological scientists, designers, and research workers. The occupational group referred to as life and physical scientists as a whole grew at about twice the national rate for all workers, but biological scientists, who make up about one-fifth of the overall scientist group, increased at the even faster rate of close to 80 percent. Nevertheless, biological scientists increased by fewer than 30,000, with most of the gain occurring among those working in hospitals and medical offices, government (particularly at the State level), and education. Women made up half of the employment increase, as their representation in this occupation rose about 13 percentage points, to 38 percent.

The majority of designers in 1972 worked for manufacturing firms, particularly in the development of durable goods. However, an increase of 80,000 in the number of designers was most strongly felt in professional and business services. Both sexes shared in the 75-percent increase in the employment of designers. Men continued to predominate in this occupation, although women increased their proportion 10 percentage points, to 30 percent.

Employment of research workers who are not included in one of the other professional occupations rose substantially in every major industry group in which researchers can be found. A doubling in the number of research workers, to 175,000, was especially evident in professional service industries, such as educational institutions and law offices. Women accounted for almost half of the overall advance and, by 1980, made up about a third of all researchers.

Managers and adminstrators. In contrast to the 1960's, which had slow growth in managerial and administrative jobs, the 1970's saw rapid advances in the employment of these workers. Jobs for managers and administrators increased nearly as quickly as those for professional workers, the fastest-growing occupational group. However, the 2.9-million increase in the number of managers was substantially less than that posted for professionals or clerical workers. Moreover, no single managerial occupation qualified in the top 20 in terms of the size of the increase, although bank officials and financial managers—with an increase of about 215,000—was in 21st place. The duties performed by different persons working in managerial and administrative positions can be quite varied, and actually fewer than half of these workers are classified according to a specific occupation under the managerial heading. That is, most managers are grouped together under the indefinite title, "managers and administrators, not elsewhere classified." The number of such workers increased by more than a third, or 1.7 million.

One adminstrative group with a relatively fast rate of growth was health administrators; their number increased by close to 80 percent, as more than 90,000 such employees—about half men and half women—were added to the job count. In line with the faster growth of health industry workers in medical facilities other than hospitals, only one-third of the increase among health administrators was attributable to hospital hirings. In both 1972 and 1980, almost half of all health adminstrators were women.

Salesworkers. The growth among salesworkers was slower than the national average, as their number rose by only about 800,000, or 15 percent, during 1972–80. The recessions of 1974–75 and 1980 had a dampening effect on this group, but, as will be seen in the discussion of cashiers in the clerical occupations, much of the actual increase in retail trade employment is reflected at the cash register rather than on the sales floor. Also, there has been a substantial rise in the number of persons who are salesworkers in their secondary job. The number of these multiple jobholders grew by about

250,000, or 75 percent, from 1972 to 1980.

Real estate agents and brokers—with an increase of almost 235,000—were 1 of only 2 salesworker categories listed among the Nation's top gainers. The growth among real estate workers can be partly traced to the tremendous rise in the investment potential of homeownership during most of the 1970's and to a growing economy's need for additional residential and commercial buildings. Moreover, saleswork can provide an opportunity for part-time employment, as about one-fifth of all real estate agents work less than 35 hours per week.[5] By 1980, half were women, as they accounted for 7 of 10 additional agents; hence, this occupation is becoming more female-dominated.

A large absolute increase also was posted among sales representatives in wholesale trade. However, their rate of growth was only about 12 percentage points higher than the national average, and their 220,000 increase occurred primarily as a result of sizable advances within a few industries—most notably the wholesale machinery equipment and supplies industry in which the employment of salesworkers grew by 70,000. The female proportion of this occupation, while still low at only about 10 percent, doubled during the period.

Clerical workers. Clericals—the largest occupational group of the 12 major job groups—took second place after professionals in terms of the 1972–80 employment advance. Like professional workers, clerical occupations included 4 of the 10 top gainers; among these were the two largest (absolute) gainers, secretaries and cashiers. Clerical workers, in particular, were affected by developments in computers and office machines, as employment decreased among stenographers and keypunch operators, for example, while increasing among computer operators.

Secretaries, who make up one-fifth of all clerical workers, registered an increase of more than 925,000, making them the leading gainer among all occupational groups. As secretaries are needed in every industry, their employment grew in all sectors of the economy, especially among fast-growing industries such as business services, welfare and religious organizations, and local government, where their employment advanced by more than 50 percent. Legal secretaries experienced exceptional growth, increasing by about 70 percent.

Only 1 of 100 secretaries is a man, and virtually all of the field's increase was among women. The traditionally female composition of the secretarial work force—as well as that of cashiers—showed no indication of changes in the 1970's.

Cashiers, whose numbers grew by more than 550,000, are strongly concentrated in the retail trade industry. Although the employment of salesworkers in retail trade was virtually unchanged, the shift to self-service drugstores, clothing stores, discount operations, and catalog stores increased the demand for cashiers. The proliferation of fast-food eating places, which often require several cashiers, led to more than a doubling of the number of cashiers working in restaurants, as well as increases in part-time job opportunities. In 1976, 4 of 10 cashiers were working part time.[6] Women made up 87 percent of all cashiers in both the early 1970's and the beginning of the 1980's.

Computer and peripheral machine operators increased by 325,000 and bookkeepers by 320,000. However, whereas the latter grew at about the same rate as that for the Nation as a whole, computer operators were the second fastest-growing occupation, following only computer systems analysts. As technological improvements have decreased the need for keypunch operators, computer operators became the largest computer occupation, accounting for nearly 40 percent of all computer personnel.[7] As was the case for programmers and systems analysts, the demand for computer operators increased in every major industry.

The need for bookkeeping services has grown in line with the overall expansion of the economy, as all industries include firms which require the services of one bookkeeper or more. Although 1 of 3 works in wholesale or retail trade, their employment grew more rapidly in other industries. Professional services, most notably medical offices, experienced a particularly fast rate of growth for bookkeepers. More than 90 percent of all bookkeepers in 1980 were women; this proportion had been slightly lower in 1972.

Another clerical occupation with a sizable increase in jobholders was that of bank tellers—85 percent or 245,000. As the suburbs expanded and branch banking proliferated, the demand for tellers increased. Apparently, the appearance of automatic teller machines served to lengthen banking hours without eliminating job opportunities for bank tellers. As has been seen, the proportion of women in several traditionally female occupations has grown, as more women have joined the labor force; this occupation is no exception. The proportion of female bookkeepers rose by 5 percentage points, to nearly 93 percent, by the start of the 1980's.

Teachers' aides (excluding school monitors) were a very small group in 1960 but grew extremely fast during both the 1960's and 1970's; their number increased by about 85 percent, or 175,000, from 1972 to 1980. These workers—who serve as teachers' assistants and thereby assume some functions formerly performed by teachers, for example, grading papers and exams, supervising study halls, and helping out in kindergartens—are almost always women. The female proportion in this rapidly growing field was approximately 94 percent in 1980, up a few points from the early 1970's.

Service workers stride ahead

While service worker jobs can be found in all major industry groups, most—nearly 90 percent—are in the service-producing sector of the economy. And as employment in this sector bounded forward, so did the number of service workers (excluding private household). The fastest-growing nonwhite-collar occupational category, it included five job groups which registered relatively large employment increases, either numerically or percentage-wise.

The occupation which ranks fourth among those with the largest numerical increase in employment was that of cooks, whose job count rose by 465,000, or close to 55 percent. Related to this increase was an almost 300,000, or 25 percent, advance among waiters (including waitresses). As more women joined the labor force, turning single-earner families into multi-earner ones, the number of restaurants and fast-food places expanded and were frequented more often. The extremely large rise in the employment of cooks, including grill cooks, pizza makers, and fast-order cooks, can also be partially accounted for by the use of several cooks simultaneously in one eating establishment. In addition, part of the increase in their employment—about 55,000—was because of more job opportunities in hospitals and other medical facilities and in schools.

About one-third of all cooks work part time—about the same proportion as for all service workers—while closer to 45 percent of waiters are part-timers.[8] Most waiters and cooks are women, but men made up an increasing proportion of the latter during the 1970's. The representation of women among cooks dropped about 9 percentage points, to 53 percent, while the female proportion of waiters remained around 90 percent.

Another group of service workers which posted a large increase was building interior cleaners (excluding janitors and sextons). Rising about 265,000 from 1972 to 1980, they experienced a growth rate about twice the national average. The number of such workers rose substantially in many industries, such as professional and business services—including building cleaning services—and in manufacturing and retail trade. The proportion of women in this occupation barely changed over the 9-year period, staying near 55 percent.

One of the fastest-growing occupations—which nevertheless totaled fewer than 90,000 in 1980—was that of welfare service aides. Their more than 150 percent increase made this the third largest gainer in the 1970's in terms of rate of growth. In 1960, prior to the widespread establishment of programs in social welfare, there were fewer than 1,000 welfare service aides. Community service workers, family service aides, and other welfare service aides work mainly in welfare and religious organizations but can also be found in medical facilities, such as nursing homes for the aged, and in schools. Current Population Survey data for 1980 show that 9 of 10 of these workers were women.

A larger service occupation, and one which also grew rapidly during the 1970's, was that of health aides (excluding nursing aides, orderlies, and attendants). Employment in this category—which includes medical assistants, pharmacists' helpers, and numerous others—was part of the overall growth of health-related occupations. Half of the nearly 135,000 rise in health aides was among those working in medical facilities other than hospitals, while a third was because of increased hospital employment. The number of women in this occupation doubled between 1972 and 1980, bringing their representation among health aides up 5 percentage points, to almost 85 percent.

Slow blue-collar growth

Blue-collar jobs, while still a major portion of the labor market with nearly a one-third share of total employment, accounted for only one-seventh of the overall increase in jobholders since 1972. The sluggish growth of blue-collar employment during the 1960's slowed even further in the 1970's as technological advances reduced the need for some types of blue-collar workers, while the job growth which took place in industries within the service-producing sector had little impact on the opportunities for workers in many blue-collar occupations. Even the rapid expansion of certain durable goods manufacturing industries—such as machinery and electric equipment—had only a slight overall effect on blue-collar employment.

Craft and kindred workers—those in skilled trades—grew at a slower pace than the overall economy but nevertheless made up more than three-fourths of the blue-collar advance, as laborers increased even more slowly and operatives employment was virtually unchanged. However, there were six specific blue-collar occupations which grew enough to qualify as big gainers, either in terms of absolute or percentage increases.

Craft and kindred workers. Much of the news concerning craftworkers in the 1970's focused on the entrance of women into the skilled trades; and, they did make important gains in this area. The number of female craftworkers doubled between 1972 and 1980, rising by about 365,000.[9] This resulted in women's representation among total craftworkers rising to only 6 percent, compared with 3.6 percent in 1972. So while 1 of 5 additional craftworkers over the period were women, and men's employment in the skilled trades rose less than 10 percent, by 1980 this occupation was still predominately male.

Heavy equipment mechanics were the only craft occupation which posted a large employment gain. Much of it took place in manufacturing, although especially rapid growth was characteristic of mechanics in repair services, wholesale trade, and mining. The rate of growth for heavy equipment mechanics as a whole was 35 percent, about 15 points above the national average. Despite the increases already noted for women in this field, the occupation was 98 percent male in 1980.

Data processing machine repairers—also called computer service technicians—experienced essentially the same sharp growth trend as other workers in the computer field, with a percentage gain that placed it as the 10th fastest-growing occupation during the period. While still not a large occupational group, data processing machine repairers increased by nearly 85 percent, as the need for installation, service, and repair of computer equipment expanded as a result of more widespread computer use. These workers were employed mainly in durable goods manufacturing, wholesale trade, and business and repair services, and the growth rate for computer technicians was virtually the same in each of these industries. Like most other craft occupations, this one is more than 90 percent men, but women did hold more jobs as computer repairers in 1980 than they had in 1972.

Operatives except transport. Nontransport operatives made up a no-growth occupational group during the 1970's and only one specific occupation under this heading—insulation workers—experienced a fast rate of growth. Moreover, only a few other nontransport operative occupations grew at a rate even somewhat above the national average; these included mine operatives, welders and flame cutters, and laundry and dry cleaning operatives. The overall standstill among operatives, following only slow growth during the 1960's, was the result of several technological and societal changes. Among these were the shift of consumer demand away from the output of goods-producing industries, in which most operatives work, and towards service-producing industries; technological advances which made production more efficient and thereby reduced the need for as many operatives to produce the same amount of goods; changes in consumer demand for some types of work, such as dressmakers; and an increase in imports of certain goods that may have limited the jobs available, such as for textile workers. The proportion of female operatives (excluding transport) edged up to 40 percent in 1980. In more than a third of the specific operative occupations, the majority of workers were women.

The almost 100-percent growth among insulation workers, bringing their number in 1980 to slightly fewer than 60,000, was the result of the need for insulation in new homes and offices and the demand for more of it among energy-conscious owners of older homes. Almost all insulation workers are men, and the majority are employed by insulation contractors.

Transport equipment operatives. Although this group as a whole experienced slow growth—about 8 percent, or 260,000, since the early 1970's—the jobs under this heading tell a mixed story: three occupations grew at rates equal to or exceeding the national average, two were unchanged, and the remaining one decreased. The fastest growing of the three gainers was busdrivers, whose employment rose about 40 percent, or 100,000.

However, in terms of the actual size of the increase, truckdrivers grew most. Their advance of 400,000 placed them fifth in the ranking of all occupations by size of their employment growth. About 40 percent of all truckdrivers work for transportation companies (including their own), and 20 percent work in wholesale and retail trade. These industries accounted for three-fourths of the job gains, with employment growing more among truckdrivers in the trade industries. Despite a number of articles and even movies about female truckdrivers, 98 percent were men in 1980. However, there were five times as many women holding these jobs in 1980 as in 1972, and their employment level rose to more than 40,000.

Nonfarm laborers. The number of nonfarm laborers, like transport equipment operatives, crept upward during 1972–80, following a decade of little or no growth. The substitution of machines for laborers, as well as the trend toward employing more highly skilled workers, depressed the hiring of laborers. Although 4 of the 9 specific laborer occupations posted employment declines, stockhandlers increased by more than 200,000 and warehouse laborers were among the fastest growing occupations.

The level of employment among stockhandlers rose by almost 220,000, with virtually all of the growth taking place in retail trade establishments (other than eating and drinking places), their biggest employer. Nearly a fourth of all stockhandlers in 1980 were women—up from 17 percent 8 years earlier—as an additional 100,000 women joined the field. More than 1 of 3 stockhandlers works part time,[10] which helps account for the large number of young persons—both male and female—holding these jobs.

Warehouse laborers (excluding those already counted as stockhandlers) rose by more than 120,000, as several major industry groups increased their hiring of these laborers substantially. Half of all warehouse laborers work in wholesale or retail trade establishments, and many others work in factories or in the transportation industry. Only about 15,000 of the employment increase can be attributed to women. Yet this represents a notable change from the early 1970's when only a few thousand women were employed in this occupation.

Yes, there were losers, too

Despite the magnitude of the employment increase during the 1970s, about 1 of 4 specific occupational groups did not post an employment advance. The declines—spread among about 50 occupations—totaled more than 2 million, ranging from 1,000 workers to more than 300,000. More than half of the 30 occupations which dropped by at least 10,000 workers during 1972–80 were blue-collar jobs, especially those of operatives. There were only five white-collar losers, four of which were in the clerical grouping. And, the same pattern occurred among the 10 biggest losers—that is, occupations whose level of employment dropped by 50,000 or more. Again, the blue-collar category posted the most losers. (See table 3.)

Occupational employment can fall in much the same way it can be boosted by changes in consumer tastes, technology, labor supply, and other factors. For example, a preference for longer hair resulted in less consumer demand for barbers, while the use of dictation machines reduced the business community's need for stenographers.

Delivery and route workers posted the biggest occupational loss—almost 310,000, or a third of the 1972 employment total. These workers, who are employed in wholesale or retail trade, in manufacturing, and to some extent by transportation and service firms, may deliver to homes or stores. The largest percentage declines were posted among those working for factories which produce nondurable goods and those employed in both wholesale and retail trade. A large drop—more than 200,000—occurred from 1973 to 1974, as many businesses were perhaps influenced by the gasoline shortage and resulting high gas prices to reduce delivery services. Employment in this occupation appears to have stabilized during the decade's second half. But despite the occupation's overall employment decline, the number of women who are delivery and route workers almost doubled during 1972–80, though the female proportion was still only 7 percent by 1980.

Table 3. Employment in occupations with declines of 60,000 or more between 1972 and 1980

[Numbers in thousands]

Occupation	Employed		Employment decreases		Rank by size of decrease
	1972	1980	Number	Percent	
Clerical workers:					
Telephone operators . .	392	316	–76	–19.4	9
Stenographers	125	64	–61	–48.8	10
Craftworkers:					
Garage workers and gas station attendants . .	502	337	–165	–32.9	5
Operatives except transport:					
Sewers and stitchers . .	936	788	–148	–15.8	6
Textile operatives	424	323	–101	–23.8	8
Transport equipment operatives:					
Delivery and route workers	892	584	–308	–34.5	1
Private household workers:					
Child-care workers . . .	543	431	–112	–20.6	7
Cleaners and servants .	713	491	–222	–31.1	2
Farmworkers:					
Farm owners and tenant farmers	1,658	1,447	–211	–12.0	3
Farm laborers, unpaid family workers	455	284	–171	–37.6	4

NOTE: Data are annual averages.

The number of private household workers has been dropping for four decades, as it fell from about 2.4 million in 1940 to 1.4 million by 1972 and 1.0 million by 1980. The two largest specific occupations within the private household workers category—cleaners and servants, and child-care workers—are among the biggest losers of the most recent decade.

Cleaners and servants totaled less than a half million in 1980, following a nearly one-third decline of 220,000 since 1972. This decrease was partially offset by a rise in employment within commercial cleaning businesses. Also, the supply of the private household workers—a group generally paid low wages—declined, perhaps more than the demand for them, as employment opportunities in other fields increased and as public assistance became more available.[11] Just over half of the cleaners and servants in 1980 were black and other minority women; however, nearly 90 percent of the employment decline among workers in this occupation took place among minority women, as older workers retired and younger, better-educated blacks entered other types of occupations. The representation of total women in this field—about 97 percent—was steady over the decade.

Child-care workers in private households, including both young part-time babysitters and full-time experienced adults, also posted a sizable employment decline. Their number dropped by about 110,000, or 20 percent of the 1972 total. During the same period, employment of child-care workers outside the child's own home—such as in day care centers or in the homes of women who care for several children—increased by 75,000, as many working parents turned to these alternatives. Moreover, much of the decrease in private household child-care workers occurred in the early 1970's, with employment in this occupation remaining relatively flat during the decade's latter half. The 1976 change in the income tax law permitting a tax credit to families with certain child-care expenses—in contrast to their early classification as an itemized deduction only—may have helped stem the downward trend of this occupation. About 9 of 10 child-care workers are white women, and most of the 1972–80 decline was among them.

Agricultural employment has dropped dramatically since the early 1900's, when the agricultural count totaled more than 12 million—or a third of all workers—

to the 1980 employment level of 3.3 million, representing just over 3 percent of all employees. Accordingly, farmworkers, who account for 4 of 5 agricultural employees, posted sizable decreases, too. Between 1972 and 1980, the ranks of farmworkers were diminished by 365,000 as farms became more mechanized and the trend towards fewer farms continued. However, it should be noted that the rate of decline among farmworkers slowed considerably during the 1970's and practically all of the 1972–80 decline took place among farmers—that is, farmowners and tenant farmers—and unpaid family workers who are farm laborers; these two groups made up two-thirds of all farmworkers in 1972. Hence, over the same period, the number of wage- or salary-earning farm laborers changed little.

Both owners and renters of small farms and unpaid laborers posted their largest losses before 1978, as their employment level held fairly steady for the balance of the decade. Interestingly, as the number of farmowners and renters declined—by about 210,000—the number of women in this occupation rose by 50,000. Still, about 90 percent of all farmers in 1980 were men.

Approximately 2 of 3 unpaid farm laborers are women, generally the farmer's wife, but his daughter or other female relative also would be included. These unpaid family members must work 15 hours or more per week on the family farm to be counted as employed farm laborers. The 170,000 drop in the number of unpaid workers is partly a response to the reduced number of family farms; the number of farms fell by half a million during the 1970's.[12] Moreover, some of the decrease can be attributed to women moving into paid jobs in the nonagricultural sector, either replacing or supplementing their hours spent on farmwork. If these unpaid farmworkers spend more hours at their off-farm job—which often happens during slack farming seasons—they are classified accordingly. Hence, the decline among farm laborers is caused by more moonlighting among some farmers' relatives and a complete cessation of farmwork among others.

A one-third decline in the number of garage workers and gas station attendants took place between 1972 and 1980. A large factor in this drop was undoubtedly the gasoline shortage of 1973, with the resulting cutbacks in the number and hours of gas stations; but probably of even greater importance was the introduction of self-service pumps. In fact, half of the overall employment drop occurred between 1978 and 1980. Garage workers and gas station attendants, many of whom are relatively young, include a substantial proportion of part-timers—about 30 percent in 1976.[13]

Two of the occupations which posted large job losses —textile operatives and sewers and stitchers—were in many ways related, as some textile firms produce the materials which are then used by sewers. A 150,000 decline among sewers and stitchers and a 100,000 drop among textile operatives—including, for example, spinners, knitters, and weavers—occurred as more efficient machinery, the use of synthetic fibers, and competition from imports have combined to reduce the demand for these workers. As about 95 percent of all sewers and stitchers are women, virtually all of the decrease took place among women. Although women represent about 3 of 5 textile operatives, about half of the reduction among these operatives was accounted for by men.

The employment of telephone operators declined by about 75,000 during 1972–80, as several factors combined to reverse their earlier upward trend. Most of the drop—about 60,000—occurred among telephone company operators, whose job total was affected by changing consumer habits, such as less use of directory assistance caused by the imposition of charges in some areas, and more direct dialing of long-distance calls. In addition, improved switching equipment reduced the need for so many operators. Private branch exchange switchboard operators, who work mainly for large companies, also experienced some decline in demand as firms adopted the operatorless Central Exchange (CENTREX) telephoning system. All of the job loss took place among women, as the number of men employed as telephone operators rose during the 1970's.

In terms of absolute size of the employment decline, those construction laborers who are employed as carpenters' helpers would qualify as the Nation's 10th largest occupational loser. Because much of their 65,000 drop undoubtedly is cyclical, rather than secular, and because the number of carpenters actually rose during the decade, a better choice of occupations for the list of those with big losses probably is stenographers.

The employment of stenographers fell rapidly during the 1970's, as their job count in 1980—at less than 65,000—was only half of its 1972 level. As mentioned earlier, the overall demand for stenographers was greatly diminished, both in the 1960's and 1970's, as a result of the increased use of dictation machines. Virtually every industry which employed stenographers in the early 1970's had drastically reduced the number of these jobs by 1980. For instance, the estimated number of stenographers working in telecommunications fell from 21,000 to 1,000; in manufacturing, their employment dropped from almost 20,000 to less than 5,000. The relative declines among public administration workers were not as large, as skilled shorthand reporters found job opportunities within the court systems. It is likely that many persons who had been classified as stenographers in the early 1970's were working as secretaries, dictaphone typists, or in other clerical fields by 1980. Employment of both male and female stenographers was reduced by about half, resulting in virtually no change in the 90 percent female share of theses jobs.

Some of the specific occupational changes of the 1970's were similar to those of the previous decade—for example, strong growth was maintained among computer specialists and cashiers, and declines continued among unpaid farm laborers. However, the employment changes for some occupations in the 1970's were in contrast to changes in the 1960's. For instance, the big winners of the 1960's included billing clerks and library attendants, which were both slower than average gainers during the 1970's; but a substantial loss was posted by machinists in the 1960's, whose number had shown strong growth during the more recent decade. How much the occupational employment trends of the 1970's continue through the 1980's remains to be seen.☐

NOTE: The data are based on 1970 Decennial Census population counts, adjusted for the aging of the population, deaths, and net migration. The Bureau of Labor Statistics has subsequently converted current CPS estimates to reflect the 1980 census, which enumerated 4.7 million more people than had been estimated in updating the 1970 figure. Because this difference was so much larger than previous censuses, historical CPS data series also are being revised, including broad occupational employment categories. Unlike data for the major labor force series, the full range of revised data for detailed occupational categories was not available at this writing; indeed, revisions of some of the detailed series may not be undertaken. However, even if revised data were available, their validity might be questionable at the level of detail in this analysis. (The size and scope of the revisions of major labor force data as a result of the 1980 census will be discussed in an article in the July *Review.*)

FOOTNOTES

[1] The Current Population Survey is a monthly survey of about 60,000 households around the Nation conducted by the Bureau of the Census for the Bureau of Labor Statistics. For all persons ages 16 and over, the following questions are asked in order to classify workers by occupation: (1) "What kind of work was . . . doing? and (2) What were . . .'s most important activities or duties?" For a listing of the job titles which made up each detailed occupation during 1972–80 see *Classified Index of Industries and Occupations,* 1970 Census of Population, U.S. Department of Commerce, September 1971. Beginning in 1983, the Current Population Survey will use the Standard Occupational Classification on which the 1980 Census of Population was based. For information detailing occupational changes between 1960 and 1970 based on the censuses for those years, see Constance Bogh DiCesare, "Changes in the occupational structure of U.S. jobs," *Monthly Labor Review,* March 1975, pp. 24–34.

Data on occupational employment are also developed by the Bureau based on the Occupational Employment Statistics (OES) surveys. The OES surveys cover wage and salary workers on the payrolls of nonagricultural establishments, except private households. Data are collected from a sample of employers who report occupational employment totals in their establishments based on specific occupational definitions on the survey questionnaire. The OES surveys are conducted on a 3-year cycle, with about one-third of the economy covered each year. To develop occupational employment estimates for a specific year, occupational staffing patterns of industries are developed from the OES survey data. These patterns are then applied to annual averages of total employment by industry from the Bureau's Current Employment Statistics Survey. The resulting data are summed across industries and added to Current Population Survey (CPS) employment data for workers not covered by the OES surveys—agriculture, private household, self-employed, and unpaid family workers—to develop estimates of total employment by occupation.

This procedure was used for the first time in 1980 to develop occupational employment estimates for 1978. These estimates were also used as the base of occupational projections to 1990 (see Max Carey, "Occupational employment growth through 1990," *Monthly Labor Review,* August 1981, pp. 43–55).

For many comparable occupations, significant differences exist between occupational employment estimates in the CPS and those based on OES survey data. These differences not only reflect sampling and nonsampling errors of each survey, but also conceptual differences. For example, the CPS is a count of individuals and therefore workers with two jobs or more are counted once in their primary occupation. On the other hand, the OES surveys count jobs, and workers on the payrolls of two employers or more (establishments) are counted in the occupation held in each establishment. More complete details on differences in occupational employment data derived from the CPS and the OES surveys are available in an unpublished paper *Comparison of Occupational Employment in the 1978 Census-based and OES Survey-based Matrices,* OES Technical Paper-1. Available from the BLS Division of Occupational Outlook.

[13] "Who's Working Part Time?"

Blacks in the 1970's: Did they scale the job ladder?

More blacks obtained white-collar jobs but fewer penetrated higher-salaried positions; mobility in higher-paid blue-collar jobs was somewhat more impressive

DIANE NILSEN WESTCOTT

The proportion of workers holding white-collar jobs has increased steadily over the past few decades as employment grew quite rapidly in the professional and clerical fields. Accompanying this movement were substantial declines among private household workers and farmworkers. Each of these trends has had an impact on the employment patterns of black workers.[1] Blacks made some advances in the more highly skilled occupational groups. For example, in 1960, 11 percent of black workers were in professional and technical and craft worker positions; by 1980, their proportion had almost doubled to 21 percent.

Throughout the 1960's, blacks advanced both socially and economically, making notable strides in a number of areas including educational attainment, voting rights, equal housing opportunities, and earnings, as well as in employment.[2] These advancements came about during a period of favorable economic conditions; however, it was also a time of social change which saw the passage of the Civil Rights Act of 1964 and the establishment of the Equal Employment Opportunity Commission. During the 1970–80 period, however, job opportunities and occupational mobility slowed considerably as the Nation underwent three recessions. With each contraction came periods of sustained and progressively higher levels of unemployment, accompanied by severe inflationary pressures which failed to subside over the course of the decade. Movement up the occupational scale for blacks progressed more slowly during the 1970's, as the number of black professional and craft workers increased only about half as fast as during the 1960's. Clearly, economic disruptions affected the occupational advancement not only of blacks, but of all workers as well.

Between 1972[3] and 1980, the number of employed blacks increased by 1.3 million, or 17 percent. Their proportion of the Nation's employed work force—9.4 percent—did not change, as the white employment level rose by 18 percent. The largest employment gains for blacks occurred in the white-collar occupations, where the four major subcategories—professional and technical, managerial and administrative, sales, and clerical—increased very sharply. (See table 1.) While their advancement in these occupational categories was proportionately greater than for whites, it was not sufficient to alter materially the overall black-white proportions of the previous decade, and blacks continued to represent a disproportionately small number of white-collar workers.

This article examines the occupational shifts of black workers between 1972 and 1980, using Current Population Survey data on employment by detailed occupation, race, and sex. To further assess the extent of occupational mobility among blacks during this period, occupational data by area of residence and usual weekly earnings are also analyzed.

Diane Nilsen Westcott is an economist in the Division of Employment and Unemployment Analysis, Bureau of Labor Statistics.

Table 1. Employment change by occupation and race, 1972 and 1980, annual averages

[Numbers in thousands]

Occupation	Black employment change, 1972-1980		White employment change, 1972-1980	
	Number	Percent	Number	Percent
Total employment	1,344	17.3	13,306	18.1
White-collar workers	1,185	55.3	10,022	27.4

Farm managers	-23	-51.1	-187	-11.4
Farm laborers	-51	-27.3	-116	-9.9

Black-white employment changes

Between 1972 and 1980, employment in the professional and technical occupations expanded rapidly, and both blacks and whites increased their participation in these fields accordingly. The number of black men in professional positions grew at a slightly faster pace than that of white males during the decade. Still, in 1980, 16 percent of all white men were employed as professional workers, twice the black male proportion. This 2-to-1 ratio is only slightly lower than that which prevailed in 1972. (See table 2.)

Relative to their white counterparts, black women strengthened their foothold as professional workers.[4] Black women professionals, who had accounted for nearly 11 percent of all employed black women in 1972, made up 14 percent of the total in 1980, a proportion approaching that for white women.

Jobs for managers and administrators also increased during the decade. Black men and women shared more than proportionately in the gains but were still much less likely to be employed in these fields than their white counterparts. For example, in 1980, 15 percent of all white men were engaged as managers or administrators, compared with fewer than 6 percent of black men.

Employment in clerical occupations rose rapidly between 1972 and 1980. Among women—who make up four-fifths of all clerical workers—the increase was proportionately much greater for blacks than for whites. Black men also increased their participation in this field, while white men experienced a decline. There was a similar occurrence in sales, where both black men and women increased their representation, while white participation declined.

Blue-collar jobs grew at a relatively slow pace during the 1970's. Overall, the proportion of black men who were blue-collar workers was down somewhat from 1972. This stemmed from reduced participation in the relatively undesirable operative and nonfarm laborer jobs, as their representation in the skilled craft and kindred trades actually rose. By 1980, the largest proportion of black men in any single occupational group was in skilled craftwork; this has long been true for white men. Despite this improvement, there were still relatively high concentrations of black men in the less skilled job categories. For example, they were still twice as likely to be in laborer jobs as their white counterparts.

After the craft trades, service work employed more black men than any other occupation. One-sixth of all employed black men were engaged in service work (excluding private household) in 1980—not much different than in 1972. Blacks continued to be more than twice as likely to have service jobs as white men.

The most substantial movement among black women during the 1970's occurred in private household work, as their proportion fell from 16 to 7 percent. One-fourth of employed black women had jobs in other service occupations in 1980—a small decline from 1972. Only clerical work was more prevalent among black women, accounting for 29 percent of those employed. Like private household workers, farmworkers registered an employment drop between 1972 and 1980; black men left this occupation more quickly than white men.

Clearly, the movement out of the lower paying nonfarm-labor, service, and farm jobs and into mid- and

Table 2. Percent distribution of employed persons by occupation, race, and sex, 1972 and 1980

Occupation	Black men		White men		Black Women		White Women

Other service workers	15.8	16.4	7.3	7.9	27.6	25.4	16.2	16.0

upper-level jobs in the white-collar occupations and craft trades was sustained during the 1970's, although the changes were not as dramatic as those which occurred in the previous decade. But while blacks moved into higher skilled (and more highly paying) occupations in greater numbers and, correspondingly, diminished their proportions in the less desirable job groups, they still accounted for a disproportionately large share of private household workers, nonfarm laborers, and transport equipment operatives, while constituting a disproportionately small share among most white-collar jobs—clerical workers being the exception.

Specific job changes

It is important to know the specific job markets in which blacks have actually made headway relative to their white counterparts. Are blacks increasingly more likely to become physicians or accountants or are they still, as in the past, finding teaching and technicians jobs their primary source of entry into the professional occupations? If the jobs blacks hold are found in the lesser skilled and lower paying professional positions, then the conclusion that there has been significant occupational upgrading may not be justified. Detailed occupational data permit a finer analysis of the areas of the job market in which blacks are overrepresented and those in which their entry seems to have been restricted. An examination of occupational participation rates[5] during the 1970's is a useful yardstick of progress in this area.

Overall, black occupational advancement in the 1970's is not particularly impressive when the detailed occupational data are examined. In most cases, black workers were concentrated in the same jobs in which they were employed in 1972. In other words, although a higher proportion of blacks could be found among the professional and technical occupations in 1980 than in 1972, they were concentrated in jobs at the lower end of the professional pay scale, such as nursing, technical trades, and vocational and educational counseling. And even though their numbers have expanded in some of the more desirable and better paid jobs, there are few examples where black men and women have been able to significantly increase their representation in a particular job.

Black men. Despite a substantial increase in the proportion of black men in the professional and technical occupations, their proportion of all employed men in this category rose only slightly over the 1972–80 period, from 4.0 to 4.4 percent. By way of comparison, black men accounted for 8.4 percent of employed men in 1980, a small drop from the 8.6 percent in 1972. The 1980 recession undoubtedly had an impact on the employment of black men. In the previous year, 1979, black men had accounted for 8.6 percent of employment, the same as in 1972. (See table 3.)

In 1980, black males in the professional and technical occupations accounted for 8 percent or more of all men employed as health technicians, nurses, social and recreational workers, vocational and educational counselors, and personnel and labor relations workers. In every case, these were the same professions in which they were concentrated in 1972.

The proportions of black men in certain higher-status professional occupations—such as accountants, computer specialists, engineers, and lawyers—showed some increases over the period, but were still disproportionately low. The proportion employed as physicians, at 2.1 percent, did not increase at all between 1972 and 1980.

The overall black occupational participation rates for managers and administrators rose slightly—but to only 3.2 percent—with bank officials and financial managers showing a healthy increase. Nevertheless, blacks in 1980, as well as 1972, were most likely to be employed as managers of restaurants, cafeterias, and bars, and as school administrators. Black employment in school administration actually declined during the 1972–80 period, while those working as food establishment managers showed a rise.

Overall, employment growth in sales was rather sluggish during the 1970's, yet black men were able to increase their proportion of those employed from 2.4 to 3.5 percent. However, gains occurred in occupations in which blacks have traditionally been concentrated—retail salesclerks and insurance agents.

Some of the largest occupational gains among black men during the decade occurred in the clerical occupations, in particular as banktellers, bookkeepers, estimators and investigators, office machine operators, statistical clerks, and secretaries—jobs that had shown substantial growth during the 1970's. For example, the participation rate of black men who were estimators and investigators rose from 3 to 6 percent and the rate for office machine operators increased from 10 to 14 percent. Areas in which black men had been highly concentrated in 1972 (15 percent or more)—file clerks, mailhandlers, messengers and office boys, and postal clerks—showed little growth or declined by 1980, although they still accounted for a significant proportion of black male employment.

To capsulize, black men were able to realize greater participation in a substantial number of white-collar occupations over the decade. One significant exception was the better paying professional and technical jobs, in which they advanced, but not significantly. Despite some progress in the professional ranks, they were concentrated in the same occupations as they were almost a decade earlier.

Blue-collar occupations expanded much less rapidly than white-collar jobs over the decade. The occupational participation rate of black men held steady for both transport equipment and other operatives, declined among laborers, but rose in the craft trades. However, even with the rise from 6 to 7 percent, the craft trades remained the only major blue-collar category in which black men accounted for less than their proportion of overall employment.

Black men increased their share in a number of the more highly skilled job categories including electricians, painters, plumbers, metal and printing craftsmen, and excavating and grading road machine operators. However, the two largest job concentrations of black men continued to be as cement and concrete finishers and crane operators.

The overall participation of black men in operative and transport equipment operative positions held steady between 1972 and 1980, with blacks continuing to represent a disproportionately large number of employed persons in these occupations. They made up about 20 percent or more of all men employed as clothing ironers and pressers, furnacemen, laundry and drycleaning operatives, sawyers, textile operatives, busdrivers, forklift

Table 3. Employed blacks as a percent of all employed men and women in selected detailed occupations, 1972 and 1980, annual averages

operatives, and taxicab drivers. For the most part, participation of black men in these occupations increased or was about the same between 1972 and 1980, because white men were moving out of these jobs.

In the nonfarm laborer and service worker occupations—which also have relatively large numbers of black men—there were declines in the proportion engaged in these jobs. The number of laborers dropped substantially during the 1970's, but the employment of black men in these occupations fell even more rapidly.

Black women. Despite the fact that they made up a smaller percentage of employed women in 1980 than in 1972—because of the huge influx of white women into the labor force—black women were able to increase their proportions in most of the professional and technical job categories. (See table 3.) And a definite occupational shift occurred over the period. In 1972, black women had participation rates of 12 percent or more in three occupations—social and recreation work, vocational and educational counseling, and personnel and labor relations work. By 1980, although they were still highly visible in these three areas, their concentration in other professional occupations had broadened considerably. The most notable change occurred in the fast-growing computer field, where black women increased their participation by 2.8 percentage points to 9.3 percent. Other noteworthy gains were among accountants, nurses, dieticians and therapists, engineering and science technicians, and vocational and educational counselors. Still, in contrast to developments in the 1960's, growth in the professional and technical occupations among black women continued to be relatively slow.

Limited gains among black women were realized in most managerial and administrative positions and sales occupations. The rate of employment participation among school administrators, insurance agents, and bank officials increased, while there was a declining rate among restaurant managers.

Black women made some progress moving out of salesclerk positions, although their participation rate actually increased during the 1970's as white women left this occupation in even greater numbers. In 1972, 75 percent of all black women in sales were retail clerks, but by 1980, this proportion had fallen to 68 percent. Black women accounted for about 5 percent of employed women in this field.

Employment gains of black women in the fast growing clerical field were widespread as their overall participation rate moved from 7 to 9 percent over the 8-year period—still somewhat below the percentage of all employed women who were black. Gains were strong for black women as estimators and investigators, mailhandlers, postal clerks, statistical clerks, and telephone operators. The largest numbers of black women were employed as cashiers, typists, and secretaries.

Although blue-collar occupations are generally male dominated, black women made a number of inroads into some job fields. It should be noted that the occupational participation rates of black women in the better paying craft trades are difficult to measure, as the actual numbers engaged in these jobs were very low. While some increases in specific crafts were registered, the overall proportion of black women in the craft trades remained about the same over the period, at 8.1 percent.

The largest concentration of black women in blue-collar jobs was in the operative category, a group in which black women have been traditionally overrepresented relative to their employment total. In 1980, black women had participation rates of 18 percent or more in six occupational categories; this compares with three such categories in 1972. Among transport equipment operatives, black women advanced rather strongly as busdrivers, reaching 13 percent in 1980. They also registered strong growth in two occupations in which they had shown little representation in the past—delivery persons and truckdrivers.

The participation rate of black women in occupations at the lower end of the earnings ladder was unchanged for laborers and declined among household workers during the 1970's. Furthermore, the drop in the rate among black women engaged in private household services, from 40 to 32 percent, is particularly important, given the large concentration of women in this occupation and the fact that black women are moving out at a faster rate than white women.

Residential location

To better understand the growth of blacks in certain occupations and their decline in others, it is helpful to examine their residential location. In 1980, approximately 55 percent of all blacks lived in central cities, with the other 45 percent divided almost equally between suburban and nonmetropolitan areas. In contrast, only 24 percent of all whites lived in central cities, with the bulk residing in suburban rings (42 percent). This concentration of blacks in the central city becomes particularly important when one realizes that it is the suburban rather than city blacks who were the recipients of most of the occupational upgrading during the 1970's.

Overall, the occupational distribution of black men and women residing in the suburbs was similar to that of their counterparts living in central cities in 1973.[6] However, by 1980, this was no longer the case. (See table 4.) While virtually all occupational changes among residents of both cities and suburbs were in the same direction, blacks in the suburbs fared better than those in the central cities or nonmetropolitan areas during the 1970's. This is evident from the rather impressive in-

Table 4. Occupational distribution of employed blacks, by sex and area of residence, 1973 and 1980

NOTE: Data include persons of black and other minority races.

creases in the proportion holding white-collar jobs, particularly professional and technical and managerial positions. For example, black suburban men had a 91-percent rise in employment in the professional fields, compared with a 16-percent increase among city residents. Likewise, black suburban women had a 158-percent increase in the managerial ranks, compared with 63 percent among their city counterparts. (These increases may be partially explained by the migration of successful white-collar blacks from the cities to the suburbs.)

In 1973, black workers in blue-collar occupations were predominant in central cities and suburban areas. However, by 1980, while both areas had made the shift to a predominance of white-collar jobs, the changes were more pervasive in the suburbs. Cities and suburbs alike experienced a drop in the percentage of men holding semi-skilled and unskilled blue-collar jobs. Metropolitan women also contributed to this growth in white-collar jobs, as they left the service occupations in great numbers.

Nonmetropolitan area blacks also moved into white-collar jobs during this period, though not to as great an extent as blacks living in the cities and suburbs. The proportion of blacks in blue-collar jobs remained unchanged between 1973 and 1980, while blacks moved out of service and farm jobs. In general, the occupational distribution of nonmetropolitan workers is very much different from that of their metropolitan counterparts in that a much larger proportion are engaged in blue-collar work and comparatively few are in white-collar occupations.

That blacks are moving into the professional, clerical and craft occupations is readily apparent, but nowhere more so than for those who live in the suburbs.[7] And that blacks are still disproportionately concentrated in the less skilled and service jobs is also evident, particularly for those residing in the city and nonmetropolitan areas. In part, central city, suburban, and nonmetropolitan employment differences reflect the strong growth of white-collar occupations in the metropolitan areas and the predominance of blue-collar jobs available in the nonmetropolitan areas. Black occupational advancement is somewhat related to residential location, in that most workers have jobs in the geographic area in which they live.[8] However, individual levels of educational attainment, skill, and ability are the predominant factors in determining one's occupational classification.

Earnings

Because the white-collar professions are considered among the most powerful and prestigious occupations in American society, it is easy to assume that the growing proportions of workers in these jobs are a sign of achievement. While white-collar jobs are often associated with higher pay status and most blue-collar and service jobs are equated with lower paying positions, movement of workers from blue-collar to white-collar jobs should not be construed as an improvement in one's relative economic position. Earnings differentials by occupation are more complex than the relationship noted above. There is a broad range of earnings within each major occupational category. (See chart 1.) In a number of instances, blue-collar trades have higher earnings than white-collar jobs, particularly those in the skilled craft occupations.

Median weekly earnings for all workers were $265 in 1980. Managers and administrators had the highest weekly earnings, $380, followed by professional and technical workers, $341; craft and kindred workers, $328; transport equipment operatives, $286; and sales workers, $279. Those occupations with earnings below the overall median were farmers and farm managers, $243; operatives, $225; nonfarm laborers, $220; clerical and kindred workers, $215; service workers, except private household, $184; farm laborers and foremen, $167; and private household workers, $94. Exhibit 1 shows specific occupations which are above or below the median level for four key occupational groups. The highest-paid professional and technical jobs—engineers, lawyers, physicians, and scientists—are all categories in which blacks were underrepresented in both 1972 and 1980. By contrast, health technologists, social and recreational workers, nurses, and teachers were among the lowest-paid professional positions and the ones in which blacks continued to be concentrated.

Black workers in management and sales professions were concentrated in jobs that paid below the median for the overall occupation. Only in the clerical field were black workers well dispersed and advancing in some of the better paying positions, such as postal clerks, stock clerks, and shipping and receiving clerks.

Blacks in the craft trades were able to advance in a number of the higher paid positions, including plumbers and electricians, though they were still underrepresented in the latter. In contrast to the professional and managerial fields, blacks in craft jobs were more widely dispersed and not relegated to the lower paid positions.

Between 1973[9] and 1980, black full-time workers increased their earnings by 68 percent, compared with 65 percent for whites. Blacks posted larger gains than whites in the blue-collar occupations, while white workers outpaced blacks in white-collar jobs. Even though blacks were entering the white-collar professions in increasing numbers, they were generally concentrated in the lower paying jobs of those particular occupations. In addition, their pay increases were smaller relative to those of whites in the white-collar occupations. Consequently, the earnings of black workers relative to whites in white-collar jobs, which had averaged 91 percent in 1973, dropped to 86 percent in 1980. However, blacks were able to advance in occupational standing in the blue-collar professions, as they increased their earnings relative to whites in a number of the higher paying jobs. (See table 5.) For example, in 1973, black transport equipment operatives made 73 percent of the earnings of their white counterparts; by 1980 this percentage had risen to 85 percent—evidence of their penetration into some of the better paid positions.

Differences in earnings by race were more discernable among men than among women. In 1980, black males made about 80 percent of the earnings of white men in both the white-collar and blue-collar occupations. How-

ever, black women made almost the same as their counterparts in white-collar jobs and over 90 percent of white women's earnings in the blue-collar trades. The following tabulation shows the 1980 black-to-white earnings differential by sex and occupation:

	Male	*Female*
Total	75.1	92.2
White-collar	79.2	98.7
Professional and technical	85.5	97.6
Managerial	76.7	105.9
Sales	69.2	99.4
Clerical	80.7	98.5
Blue-collar	81.4	93.9
Craft	86.9	99.5
Operatives, except transport	86.8	94.3
Transport equipment operatives	82.6	97.2
Laborers	86.2	100.6
Service	86.6	102.7
Private household workers	73.5	140.7
Other	86.6	103.9
Farm	78.3	81.4

Black women, while still at the bottom of the earnings hierarchy, have narrowed the earnings gap between themselves and white women in most occupational cate-

Table 5. Earnings data by race and occupation for May 1973 and second quarter 1980

Occupation	Percent increase in earnings, 1973–1980		Black/white earnings ratio	
	Black	White	1973	1980
Total	68.2	65.4	79.6	81.0
White-collar workers	53.2	63.6	91.3	85.5
Professional and technical	58.3	57.5	89.7	90.2
Managers and administrators	42.4	58.2	87.9	79.1
Sales	76.9	64.0	71.3	77.0
Clerical	47.5	63.6	107.8	97.2
Blue-collar workers	77.2	69.9	77.9	81.2
Craft and kindred workers	61.7	66.5	84.8	82.3
Operatives, except transport	77.4	70.4	85.2	88.7
Transport equipment operatives	69.9	63.6	73.3	85.1
Nonfarm laborers	58.0	56.6	83.2	83.9
Service workers	74.0	65.1	88.1	92.8
Private household workers	123.5	157.6	154.5	133.1
Other service workers	67.0	64.3	92.0	93.3
Farmworkers	73.7	67.3	75.2	78.1

NOTE: May 1973 data are for black and other races; second quarter 1980 data are for blacks only.

gories, much more so than black men have succeeded in doing with respect to white men. This is because women are more concentrated in lesser skilled, lower paying jobs which traditionally have been easier for blacks to enter.[10]

Overview

Black occupational status improved somewhat during the 1970's, as proportionately more blacks moved into white-collar jobs, although few penetrated the higher-salaried professional and managerial positions. In fact, the black-to-white earnings differential was unchanged for professional and technical workers between 1973 and 1980, and, even more importantly, black earnings relative to those of whites fell in the fast growing clerical field. Black mobility in the blue-collar, service, and farm occupations was more impressive, as blacks moved out of unskilled work—especially private household and laborer positions—and into the craft trades. The growth of black employment in the expanding skilled craft area was particularly important, in that blacks were able to move into some of the better-paid positions, and, for the most part, were able to increase their earnings relative to their white counterparts in the blue-collar occupations.

Overall, shifts by blacks into the higher-salaried occupations were rather limited; this was most apparent for those who resided in the central city areas. The majority of blacks lived in central cities, which have high concentrations of office and other business district-type activities. Yet, by 1980, central city blacks had made little progress in increasing their proportion in white-collar occupations. Most of the occupational upgrading occurred among the smaller number of blacks who resided in suburban areas. Furthermore, the progress that did occur among blacks living in the city was mostly accounted for by women, whereas, in the suburbs, black men and women shared equally in the gains. This indicates that black women in both areas competed successfully for jobs in those occupations in which women are heavily recruited. Clearly, black workers, especially black men and city dwellers, need to gain more access to the higher-skilled, better-paying jobs in the rapidly growing white-collar fields, if their earnings are to increase. ☐

NOTE: The statistics are based on the 1970 Decennial Census population counts, adjusted for the aging of the population, deaths, and net migration. The Bureau of Labor Statistics has subsequently converted Current Population Survey estimates to reflect the 1980 census, which enumerated 4.7 million more people than had been estimated in updating the 1970 figure. Because this difference was so much larger than previous censuses, historical CPS data series are also being revised, including broad occupational employment categories. However, the full range of revised data for detailed occupational categories was not available at this writing; indeed, revisions of some of the detailed series may not be undertaken. Even if revised data were available, their validity might be questionable at the level of detail in this analysis. (The size and scope of the revisions of major labor force data as a result of the 1980 census will be discussed in an article in the July *Review*.)

——— *FOOTNOTES* ———

[1] Unless otherwise stated, the term "black" in this article refers exclusively to the "black only" population and not to the "black and other" category which is made up of blacks, American Indians, Alaskan Natives, and Asian and Pacific Islanders.

[2] See Sylvia Small, *Black Americans, A Decade of Occupational Change*, Bulletin 1760 (Bureau of Labor Statistics, revised 1972). For a short history of occupational change among blacks, see "The Social and Economic Status of the Black Population in the U.S.: An Historical View, 1790–1978," *Current Population Reports*, Series P-23, No. 80 (Bureau of the Census), pp. 61–63.

[3] The year 1972 was chosen for comparison with 1980, rather than 1970, because occupational data before that time are not strictly comparable with data for later years due to classification changes.

[4] For a recent analysis of the employment situation of black women, see Phyllis A. Wallace, *Black Women in the Labor Force* (Cambridge, Mass., MIT Press, 1980).

[5] For the purposes of this analysis, an occupational participation rate is defined as the ratio of black men employed in a given occupational group to all men in that occupation and black women to all women. It is appropriate to examine data for men and women separately, as occupational differences between the sexes are so pronounced. Though this statistic is not unique, the term "occupational participation rate" was made popular by Stuart Garfinckle back in 1974 in his article, "Occupations of women and black workers, 1962–1974," *Monthly Labor Review*, Nov. 1975, pp. 25–35.

[6] Data by area of residence are not available for 1972. Also, the

term "blacks" in this section refers to persons classified as blacks and other minorities, as area of residence data by occupation are not presently available for the "black only" category.

[7] For a detailed account on the growth of white-collar jobs by area and how it relates to black employment, see Brian J. O'Connell, *Blacks in White-Collar Jobs* (New Jersey, Allanheld, Osmum and Co., pub., 1979). Also see Thomas M. Stanback, Jr. and Richard Knight, *Suburbanization and the City* (Cambridge, Mass., Ballinger Publishing Co., 1974).

[8] See Diane N. Westcott, "Employment and commuting patterns: a residential analysis," *Monthly Labor Review*, July 1979, pp. 3–9.

[9] Earnings data used in this article are collected through the Current Population Survey. For purposes of comparability, it was necessary to compare May 1973 data with that for the second quarter 1980, as earnings data were not available on an annual average basis prior to 1979. Also, data for black and other races were the only race data available in 1973; by 1980, however, earnings data were tabulated for blacks only, excluding other minorities. Hence, the data are not strictly comparable but do provide very close estimations of earnings changes during this period for blacks.

[10] The earnings gains of black women have been attributed to a reduction in racial discrimination among the female sex. For an explanation of these and other findings on black male/female earnings, see Ronald N. Oaxaca, "The Persistence of Male-Female Earnings Differentials," and others in F. Thomas Juster, ed., *The Distribution of Economic Well-Being* (Cambridge, Mass., Ballinger Publishing Co., 1977).

Dividends for two

Under the social security system of Old-Age, Survivors, and Disability Insurance the two-worker family "receives more insurance protection for its 'investment' than does the one-worker family with an equal income. If one worker in such a family retires before the other, then benefits will be paid to that worker. On the other hand, in the one-worker family, no benefits are payable to the nonworker unless the worker retires. Also, child survivor benefits are payable in the event of the death of either spouse in a two-worker family, but only on the death of one spouse (the worker) in the one-worker family. Further, prior to retirement, both spouses in the two-worker family have disability insurance, whereas in the one-worker family only the working spouse does."

Labor Department's first program to assist black workers

The philosophy of equal employment opportunity began with the Department's Division of Negro Economics, created to mobilize black workers for the war effort; however, the project was ahead of its time, and efforts to make it permanent were not successful

HENRY P. GUZDA

Sixty years ago, the Division of Negro Economics, one of the great, yet virtually ignored experiments in the history of the Department of Labor, ceased operation. Long before equal employment opportunity became a priority, this division promoted the concepts of that philosophy. The largest demographic shift of blacks in this Nation occurred between 1915 and 1920, and the division assisted many of these migrants in obtaining employment and in finding suitable housing, advised them on business and financial matters, encouraged racial harmony in the workplace, and even devoted attention to the issues of female workers.

Born amidst the feverish demand for workers during the first world war, the Division of Negro Economics was dismantled as part of an alleged return to prewar "normalcy." But, prejudice played a significant role in the division's demise. Despite its generally conservative approach to racial issues, the division made enemies during a period which historians agree was not conducive for promoting black aspirations. Subsequently, officials of the Labor Department did not accomplish all they set out to do. They did, however, plant the seed, and although slow in developing, the dreams of the 1920's finally started to bloom in the 1960's and 1970's. A pioneer in the civil rights movement succinctly evaluated this noble experiment stating: "This division, though handicapped by the turmoil of transition general in the federal government and by the past Congress, has made an excellent beginning [in fostering economic and social justice]."[1]

The Department of Labor's novel and progressive program to assist black Americans, juxtaposed against that of most other cabinet-level agencies in the administration of Woodrow Wilson, was the result of the enlightened leadership of Secretary of Labor William B. Wilson and his Assistant Secretary, Louis Post. Post, in particular, had a great interest in the civil rights movement as a cofounder of the National Negro Conference of 1909 (the forerunner of the National Association for the Advancement of Colored People—NAACP). An admirer commented on Post's devotion to justice stating, "He dared in a trying time, to defy the forces of madness, hatred and greed."[2]

South to North exodus

Beginning in 1915, blacks began moving from the South to the industrialized North. When the First World War erupted, in 1914, in Europe, cutting off the flow of immigration to the United States, industrialists looked for a cheap, preferably nonunion, source of labor to replace the Hungarians, Poles, Italians, Czechs, and other foreign nationals who, heretofore, had represented the bulk of the unskilled work force. Blacks, seeking to escape the economic poverty and repression of the South, answered the call.

The extent and composition of the migration fostered concern among varied interests. Southern employers, especially farmers, feared that the depletion of their tradi-

---

Henry P. Guzda is a historian in the U.S. Department of Labor.

tional labor supply would imperil their economy. Northern trade unionists felt that the additional number of workers in the labor market would play into the hands of those employers who wanted to destroy organized labor. J. H. Walker, president of the Chicago Federation of Labor, for example, claimed that certain employers in Illinois financed agents to recruit black workers, transporting them free of charge to the North to work for submarginal wages and to act as a reserve corps of strikebreakers.[3]

To assess the migration problem, the Labor Department contracted with Dr. James Dillard, a leading civil rights leader of the period, to conduct a study. Dillard found that blacks did not saturate the northern labor force. He also reported that as the southern economy changed from labor-intensive cotton crops to mixed farming with fewer demands, blacks left the South to take advantage of economic opportunities in the North as well as to escape repression.

A few weeks after the report's release, Lathrop Brown, special assistant to Interior Secretary Franklin Lane, addressed the migration issue. He brashly claimed that the stringent prohibition laws prevalent in the South, and the lack thereof in the North, was the reason behind black migration. Assistant Secretary Louis Post complained to Interior Secretary Lane that Brown's specious remarks would only serve to embarrass the Administration, that Labor Department studies proved that the inducement of higher wages, not prohibition, was the cause for the migration.[4]

Calls for black adviser answered

Incidents such as these demonstrated to advocates of social justice that they had friends in the Department of Labor. As a result, many concerns inquired about the possibility of a black labor adviser in the Department to deal with the problems of black wage earners. Even private citizens saw the Labor Department, or its function, as an appropriate guide rail to assist black economic advancement. As early as 1913, Thomas Swann, a private citizen, suggested to President Wilson that he establish an advisory body of blacks to help the wage earning members of their race. In 1917, a New York City minister, Richard Bolden, requested that the President appoint a black man or woman to represent the labor interests of black Americans.[5]

Not until America's entry into the world war, in 1917, however, did either Secretary Wilson or Assistant Secretary Post think it opportunistic to appoint a black adviser. Racial issues were "delicate and difficult," and neither official wanted to embroil the young Department—created in 1913—in a major controversy. But, because the Department was responsible for allocation of the Nation's labor force for the war effort, the two officials thought it more than just to attend to the labor concerns of approximately 12 percent of America's working population. As a result, Wilson, Post, and the representatives of seven major civil rights organizations, including the NAACP and National Urban League, worked out a basic agreement to establish a "Division of Negro Economics" in the Department of Labor. The purpose of this division was to mobilize the black work force in the United States, and also to work for the general advancement of black wage earners.[6]

While the chief of the Division of Negro Economics and a small staff would be part of the secretary's office, the majority of personnel, including 15 state representatives and 134 examiners, stenographers, and secretaries, would be incorporated within the existing framework of the U.S. Employment Service. Assistant Secretary Post and his superior feared that the creation of an independent black division would cause criticism from some blacks who would view it as a "jim crow bureau," and from segregationists who would oppose any black-oriented program encouraging interracial harmony. The arrangement worked to the division's advantage, because it could make use of the already established employment procurement functions and facilities of the Employment Service.[7]

The infrastructure of the division included integrated local advisory committees. These committees, composed of volunteer white and black community members, monitored social, cultural, and employment conditions at the job sites. The committees worked under the guidance of State representatives from the Division of Negro Economics to ameliorate racial problems. These advisory committees completed a linkage of Federal-State-local cooperation, and the flexibility of this network achieved some remarkable results.

Before the program could be implemented, Secretary Wilson and Assistant Secretary Post faced the task of picking a division chief. Many candidates offered their services or had someone promote them, but Giles Jackson ran the most aggressive campaign for the job. A black politician from Richmond, Va., he sought and gained endorsements from both of Virginia's U.S. Senators, the American Federation of Labor, and the White House. Wilson almost offered him the job when Louis Post interceded.[8]

Jackson was *persona non grata* with most of the black community, and they let Assistant Secretary Post know their displeasure. *The Washington Bee*, a black newspaper, sent an editorial to Post saying that Jackson was not fit to be a dog catcher, let alone the representative for the black working class. W.E.B. Dubois begged Post to reconsider, calling Jackson "one of the most disreputable characters the Negro race has produced." Even Post himself had doubts about Jackson's character and competency.[9]

On May 1, 1918, Secretary Wilson chose another candidate, George E. Haynes, professor of Sociology and Economics at Fisk University in Tennessee, to head the Division of Negro Economics. A recognized scholar and authority on the black migration phenomenon, a cofounder of the National Urban League, and the first black American to receive a Ph.D. from Columbia University, Haynes was most qualified.[10] He announced that although his primary responsibility was to mobilize the black work force for the war effort, achieving cooperation of the races and opening the doors of opportunity to blacks was equally important.

State programs established

Although planned and programmed at the Federal level, the Division of Negro Economics was basically State and local oriented. It was on that level that interaction between the races was most intimate. Haynes wanted to make sure that the transmission of the Labor Department's program to the people it intended to help was clear and direct. Therefore, he personally assisted in founding the State branches.

Haynes bearded the lion in its own den, establishing the first State division in the South, where opposition to race-related programs was the strongest. To stir up an aura of good feelings, a massive public relations rally was held to "kick-off" each State's program. At the first rally in Raleigh, N.C., Haynes told the large audience, speckled with white and black faces, that blacks wanted to help win the war and share the bounties of the Nation.

With flourishes of rhetoric that paled some of the propaganda statements of George Creel's Division of Information (an agency designed to sell America's involvement in World War I), Haynes' related acts of patriotism performed by blacks, stating they were among the first American soldiers to sacrifice their lives in the trenches of France. He added that on the homefront blacks had accomplished different feats of patriotism, citing as an example the black riveter in a Baltimore, Md., shipyard who drove a record 4,875 studs in 1 day into a vessel under construction. Many black Americans, claimed Haynes, demonstrated their patriotism every day and in doing so destroyed many of the prevalent myths about racial inferiorities.

The rally was a success. Immediately afterwards, the first local advisory committee was formed. It consisted of 30 influential residents, white and black, including the Governor of North Carolina. In 6 months, the spirit of good will generated at the rally helped in the establishment of more than 25 advisory committees throughout the State. The best indication of the rally's influence was in a letter to Assistant Secretary Post from North Carolina's Governor Bickett who called it, "the most helpful and patriotic conference I attended."[11]

Following close on the heels of the North Carolina experiment, Haynes proceeded to establish offices in other States. In Virginia, the second State targeted by Haynes, a different approach to stimulation of good working conditions took place. Virginia's Division of Negro Economics representative, T.C. Erwin, assisted the U.S. Housing Bureau in planning and building 254 modern residential units for blacks near Richmond. Erwin, like Haynes, believed that better living conditions would make healthy, contented, and stable workers. Erwin also assisted in organizing a cooperative savings and loan institution to pay off the mortgages on the units, and a governing council to impose rules and regulations on the community.

Racial issues were not always so pleasantly natured. In Norfolk, the division ameliorated a potentially riotous situation. This busy port city suffered from a shortage of stevedores to load and unload cargo from merchant ships. The local Chamber of Commerce wanted the city council to pass "work or fight laws," mandating that able bodied men work at war-related jobs or face conscription into the Armed Forces. Blacks viewed the laws as alternative forms of slavery, directed at them disproportionately when compared to whites. Erwin persuaded the city council to delay action; he held a job fair and in 2 days recruited more workers than there were jobs to fill. These newly hired blacks received wages equal to their white counterparts, which would not have been the case under work or fight laws, and the praise of the local press for demonstrating their patriotism.[12]

As the division moved deeper into the South, the problems facing it became more difficult and serious. For example, in Mobile, Ala., some employers were exploiting black workers to the degree of slavery, and neither the local advisory committee nor the State's Division of Negro Economics representative could get them to stop. Haynes tried to meet with the local Chamber of Commerce, hoping to persuade the business group to pressure their colleagues to act humanely, but they refused to see him. This brought a visit from Assistant Secretary Post who told the chamber that many of the employers in question held government contracts and could forfeit them if the problems were not remedied. A high ranking official of Tuskeegee University in Alabama wrote Haynes: "Mr. Post's visit here did a lot of good in the matter of putting a stop to some of the injustices practiced against colored labor. I do not mean to state that these [employers]. . . have come over to the Lord's side . . . , but they have desisted from some of the more flagrant abuses practiced."[13]

In the North, the Division also demonstrated a versatility. The basic format of organizational activities, a rally, the founding of a State branch, and the founding of local advisory committees, was the same, but with a few twists. Residential restrictions against blacks created a severe housing shortage, and some employers, not with altruism in mind, operated boardinghouses to keep black workers near the job sites. Local advisory committees monitored the conditions of these houses and reported violations to the State's Division of Negro Economics representative. At times, employers cooperated and corrected the situation; too often it took threats of debarment from government contracts.[14]

Throughout the North, the division made great strides towards benefiting black wage earners, while stimulating stability for the production of war materiel. In Chicago, the division, often working out of the offices of the National Urban League or the Young Men's and Women's Christian Associations, provided employment offices that informed blacks of job opportunities or residential openings. The local representative encouraged strong community roots by helping blacks invest in cooperative stores and savings institutions. In New York, State representative Jesse Thomas helped break the color barriers in the city retail trade by convincing Gimbel's department store to hire blacks. And, in Detroit, Mich., the division successfully encouraged the promotion of some workers into supervisory positions. Also in Detroit, the American Car Foundry praised the division telling representative William Jennifer, "your labors . . . will be crowned with the success it deserves."[15]

Problems of black women exposed

According to a Division of Negro Economics special report on black women, the great labor shortage during the war, especially in northern industries, gave black women the opportunity to enter industrial pursuits never opened to them before. The study of working conditions of black women exposed many problems that would not become topics of scrutiny for another 25 years. In addition to the conditions of employment, wages, hours, and standards, the report also touched on discrimination against black women and how such practices could be prevented. It even recommended that black women be promoted into supervisory positions as rewards for competent performances, an almost unheard of proposal 1 year before women had the right to vote.

The special study was as revealing as it was clairvoyant. It disclosed that black women suffered occupational discrimination *vis a vis* white women, the same as black men did in relation to their white counterparts. The report claimed this reached ludicrous proportions in perpetuating racial discrimination and stereotyping. Blacks were precluded from skilled jobs because employers thought them inferior to whites. This, said Helen B. Irvin, coauthor of the report, was totally false. She found, among many cases, a cigar maker who employed fair-complexioned black women in skilled positions "in order that they may be regarded by patrons as Cuban, South American or Spanish."[16]

The unabashed forms of discrimination were not confined to the private sector. Irvin found black women in the Federal Government working at the least desirable jobs, with the specter of unemployment hanging over their heads when the soldiers returned from the war. She labeled this a guise for blatant discrimination, stating, "Others were frankly told that such position as remained available were intended for white workers, and that they had been used merely because no others could be obtained . . . ."[17]

Concluding on a more positive note, the report predicted that the Federal Government would be the primary means of breaking the bonds of segregation and discrimination. Irvin predicted that black female workers would be rewarded in the future with promotions and job security in the Federal Government, and that it was not too far in the future that this would come to pass. Unfortunately, the time span was considerably longer than even she expected.

Fight for survival

As the war began to wane, it affected industrial production in tandem, and the Division of Negro Economics again demonstrated flexibility in handling new situations. The transition from a war to a peacetime economy, if precedents held true, meant the laying off of most black workers. The projections of unemployed blacks, packed into ever growing slums and facing daily diets of poverty and dispair, appeared imminent.

The division wanted to deter this grim prophecy. The local advisory committee in Pittsburgh, Pa., negotiated an agreement with the Carnegie Steel Co., for the retention of one-third of the black workers it employed during the peak of wartime production. This agreement set a precedent, as several other steel companies in the valleys washed by the Allegheny and Monongehela rivers instituted similar plans. Unfortunately, some steel companies, as well as other industries, retained black workers only to thwart the growing trend towards industrial unionism—some employers used the black workers as strikebreakers and union busters, particularly during the brutal and violent steel and meatpacking strikes of 1919. But despite this, Haynes still thought that the worker retention plans "show to a small degree some of the practical work accomplished by this division within a short period of time."[18]

The welcomed winds of peace bore ill tidings for the Division of Negro Economics. Promises of social and economic justice, if not social acceptance, looked bright and meaningful before the armistice. But, once the peace was consummated, submerged racial antagonisms crept towards the surface. Indicative of the changing atmosphere was a series of race riots which swept across the Nation, crippling Detroit, Washington, Chicago, and other cities.

The first signs of trouble for the division came from Florida. In April 1919, Governor Sidney Catts requested that the Department of Labor abolish the Florida Division of Negro Economics, and at the same time replace the head of the U.S. Employment Service (who was white) with a personal friend he described as "a real Florida cracker." Catts accused the Division's "carpet-bag negro federal officers" of inciting riots by promulgating the amalgamation of the races. "I am looking upon this question as a white man," he said, " . . . I could look upon it from no other viewpoint . . . . "[19]

Assistant Secretary Post found Catts' remarks specious at best. The State representative had been a mechanic, teacher, and businessman in Florida for a number of years and was respected by many influential white persons of the State. Secretary Wilson, temporarily suspended the division's program until he could investigate Catts' charges, but later reinstated it.

The Florida dispute was only a harbinger of future problems. A few weeks later, the *New York Tribune,* quoted an unnamed U.S. Senator who complained that irritation over the use of black labor conciliators in the South had reached a high point from the Atlantic Coast to Texas. "If Secretary Wilson, and more particularly Assistant Secretary Post," said the unnamed source, "do not pull in their horns very promptly, it will topple the cornerstone of the Democratic South.[20]

Tensions increased and criticism became uglier. At the convention of the southern-based National Lumber Manufacturers Association, in 1919, the association's president, John Kirby, expressed displeasure over the division. Referring to the Labor Department's request for a conference to iron out difficulties, Kirby told the audience, "I shall be glad to confer with Mr. Wilson or Mr. Post, but when it comes to sitting in counsel with Dr. Haynes, a negro, you will have to excuse me. In the South we tell negroes what to do; we do not take counsel with them." A reporter covering the convention wrote, "his audience broke into a storm of cheers when the speaker dramatically told of refusing to sit with a negro."[21]

Battle lost

Criticism and condemnation only convinced officials of the Labor Department that the division should become permanent. "I desire for the Division of Negro Economics to be continued," Secretary Wilson wrote to Louis Post. Apparently, Wilson also informed Haynes of this, for Haynes, in a confidential letter to his New York representative, wrote, "the Secretary wants to make it [the division] permanent." In fact, Secretary Wilson, as early as 1918, submitted a bill to the Congress to accomplish this task, but it died in committee. As an alternative, the Secretary proposed funds for the division in the appropriations request before the Congress.[22]

In the Congress, the division's friends and foes met to decide its fate. An optimistic Haynes said, "on every side, everyone who has looked into it commends the work as valuable and necessary, but no one can tell what Congress will do."[23] When the bill came before the labor committee, an unnamed legislator raised a parliamentary point of order over funding, claiming that the Secretary of Labor, by creating a public agency, usurped powers mandated to the Congress, and that the issue of appropriations was moot. The conferees upheld this point.

The issue of usurpation of powers was a ploy. Section 4 of the organic act creating a Department of Labor allowed the Secretary to appoint special advisers and utilize them in a cooperative effort with other branches of government. Solicitor of Labor John Abercrombie cited similar cooperative efforts, including those in the U.S. Public Health Service and the War Risk Insurance Bureau of the Treasury Department. Apparently none of this impressed the committee, and the division faced extinction with the beginning of fiscal year 1920.[24]

Civil rights leaders fulminated with anger. Mary White Ovington of the NAACP accused the Congress of unabashed racism; Eugene K. Jones of the Urban League expressed shock and sorrow over the Congress' shallow excuses; and T. J. Woofter of the Phelps Stokes Foundation called the action "sheer political chicanery."[25]

But the division was not yet dead, only critically wounded. Haynes and Assistant Secretary Post drafted new legislation for the next session of the Congress (in 1921), and Secretary Wilson transferred funds from other appropriations to maintain a skeleton Division of Negro Economics. Haynes' services were shared with the Inter-Church World Movement which, in turn, paid part of his salary. The U.S. Conciliation Service absorbed some of the division's personnel, but programs and activities were drastically suppressed. Local advisory committees, without central direction, began to disperse, decay, and finally disappear.

One last gasp of hope remained. The Congress could legislate the division into existence, and some heavy lobby pressure by civil rights groups resulted in hearings on a bill. Haynes testified as the official Labor Department representative, arguing that such a Federal agency would help improve race relations in the Nation and coordinate local efforts to achieve racial harmony and equal opportunity. Such a program, said Haynes, could only be administered at the Federal level.

Haynes' appeals fell on deaf ears. Senator Francis Warren of Wyoming expressed the general feeling about the bill's chances, stating: "You are exactly equal under the law. You are exactly equal, of course, under those appropriations. But as far as we are concerned, there should not be division between different classes of workmen, one against the other . . . we have to look at it with the idea of preserving equality. The same rule applies to both."[26] Haynes retorted, "the fact is Senator, that heretofore the inequality has rested the other way when it has come to matters of industrial opportunity and employment."

No clever repartee, however, could change the outcome. In 1921, a new Administration took over, and with it came a new chief of the Labor Department, James J. Davis, who showed little interest in fighting for the Division of Negro Economics' continuance. The division limped along for another year before succumbing to neglect and disuse. Even though its death was neither a cause nor an effect for the growth of slums and poverty or the escalation of unemployment rates among blacks, it is conceivable that its continued operations might have at least improved conditions. Unfortunately, the program was too advanced for the time in which it existed. ☐

[7] Criticisms that the Division of Negro Economics was a segregated branch of the U.S. Employment Service were based on ironic twists of fate. The immediate personnel of the division were black because its chief believed that they could better relate to black problems. The offices which housed the division branches did not have segregated facilities. In fact, the first recorded case of what now is called "reverse discrimination" may have occurred when Jesse Thomas, the division's representative in New York, told the USES director he did not want the loan of a white secretary, saying, "although I have no objections professionally, I prefer a 'colored' girl." Human capital and multinationals: evidence from Brazil and Mexico

RICHARD U. MILLER AND MAHMOOD A. ZAIDI

Although the theoretical and empirical literature dealing with economic growth is by now quite extensive, one cannot say the same for the issue of human capital and development. In the first place, much of the research has been carried out in the industrialized countries.[1] Moreover, those studies that deal with less developed countries have focused almost solely on returns to general training or education without touching those questions associated with on-the-job specific training.[2]

This void in the human capital literature is particularly important from the standpoint of less developed nations, given their reliance on economic development via industrialization and the preeminent role in this process assigned to foreign capital. For example, it is not clear to what extent investment in general education actually pays off in higher earnings for those workers either aspiring to or gaining access to the modern sectors of a developing country. Related questions also involve the emergence of credentialism as a consequence of general education investments; the incidence of specific training in modern-sector firms and its payoffs, the way in which training investments are funded and who bears the costs in such firms; and so on. Without adequate evaluation, educational policy may not only be ineffectual but may, in fact, produce negative consequences.[3]

Broadly speaking, two competing hypotheses may be considered. The first is that the presence of multinational corporations in a host country stimulates investment in human capital. This could result either from on-the-job and other training (and other human services) provided by the multinational corporation to its employees, or from an increased incentive for the domestic population to engage in schooling and "off-the-job" training. Such incentive is presumably the result of the presence of modern-sector jobs provided by the multinational corporation. Alternatively, it may be argued that multinationals contribute only marginally to the development of human capital in less developed countries because they tend to import capital intensive technologies which imply the need for relatively few skilled employees who may themselves be foreign nationals.

To evaluate these hypotheses, we expanded the standard human capital model proposed by Jacob Mincer,[4] and tested its applicability to particular multinational corporations in developing countries. (For a discussion of the model, see the full paper.)

An alternative to the education-productivity-earnings relationship of the human capital model is the screening hypothesis, or theory of credentialism, which asserts that employers prefer better educated workers for reasons other than increased productivity. Therefore, they will treat educational qualifications merely as a screening device when hiring new workers.[5] It is argued that the employer's main concerns are with trainability and with administrative expedience. Hence, as educational levels rise in a society, so too will the educational hiring standards. If this hypothesis is confirmed, the implications are enormous, particularly for a developing country. First, cohorts of older workers may become increasingly disadvantaged vis-à-vis younger workers and society may thus become more stratified. Second, returns to education may be more highly correlated with starting wage than with long-term earnings. Third, the incidence of credentialism may be highest among those firms with the strongest internal labor markets, that is, modern-sector multinational firms, thereby con-

tributing further to occupational and economic stratifications. And, finally, from a general social standpoint, educational expansion in general is unlikely to have much impact on earnings differentials. The results of our model do not provide hard evidence for or against the screening hypothesis, but we were able to draw certain conclusions from ancillary data on our sample of workers.

The incidence and costs of on-the-job training are generally considered to be more difficult areas of human capital theory to deal with conceptually and empirically. As one observer points out, "From the earliest formulations of the human-capital model by Schultz, Becker and Mincer, it was on-the-job training and not formal schooling that was taken to be the paradigm case of self-investment."[6] Yet the difficulties in measuring returns to such investment grew as it became clear that it was possible to identify a number of forms of on-the-job training, for example, general versus specific training, or training which occurred under supervision versus that acquired simply by doing. Training might, in fact, be acquired off the job but while still employed by the firm and this, too, might be general or specific. Thus, simply to speak of general versus specific training or even off-the-job versus on-the-job training is methodologically inadequate. However, our model has obvious shortcomings concerning the identification and measurement of who bears the training investment costs and who reaps the returns. Therefore, alternative information was analyzed to answer these questions.

The data for this analysis were collected in Mexico City in 1975–76 and in Sao Paulo, Brazil in 1977, and consist of a 10-percent random sample of employees at one plant or location for two American multinational firms in each country. In order to standardize the data as much as possible, the main sample is composed of workers from the same auto manufacturing and retail trade firms in Mexico and in Brazil. In addition, supplementary data were also gathered in Brazil from two other U.S. multinational corporations and from a large Brazilian utility company. The total sample consists of 1,137 workers.

The findings

According to ordinary least squares results from our regression model, the current wage was, almost without exception, not significantly associated with such variables as previous training, current training, and years of work experience prior to current employment in the firms in Brazil, but prior work experience was significant in the Mexican branches. However, education and tenure were significantly related in both countries.

The above findings lend themselves to several conclusions. For example, prior experience and training do not seem to pay off directly in higher earnings in the Brazilian firms as one might expect if they were a form of specific investment in human capital that workers have paid for. Rather, they enhance the credentials of the job applicant, helping him or her to gain access to the modern sector, or they represent investments that workers did not pay for. Education, however, clearly both enhances credentials, and provides a direct payoff. In the Mexican firms, prior work experience, education, and tenure all are beneficial to the employee.

The fact that our tenure and experience variables were significant raises questions for which the answers can be only speculative. However, if one assumes that as work experience increases, so too will skills, knowledge, and productivity, our findings may indicate returns to learning by doing. Because this assumption seems plausible, the tenure and experience results, along with the significant coefficients on education, appear to support the hypothesis that multinational corporations do reward individuals for investments in human capital.

Regarding the credentialism hypothesis, our interviews and data suggest that such screening occurs in both Mexico and Brazil. In the auto assembly plants, managers freely admitted that 80 percent of the work required no previous experience or skill, and another 16 percent could be classified at best as semi-skilled. Yet these same firms hired no one without at least the completion of primary education. For example, the mean years of education at the date of hiring at the Mexican auto plant had increased from 4.8 years during the 1940–50 period to 6.9 years during 1970–80 with no corresponding increase in job requirements. In both Mexico and Brazil, this educational criterion would effectively shut out 65 to 70 percent of the urban job seekers and nearly all the urban migrants.

To analyze the incidence and costs of on-the-job training in our main sample of firms, we differentiated between the auto companies and the retail trade organizations. In the former case, formal on-the-job training is almost nonexistent. The basic approach is learning while doing. Perhaps 4 percent of the workers get formal training and another 16 percent are permitted, *on their own time*, to practice other jobs and prepare themselves for promotion.[7] The retail trade firms were much more inclined to engage in formal on-the-job training, averaging better than 3 months of such training among the workers surveyed.

Those modern-sector firms that employ primarily blue-collar workers show a marked reluctance to bear the costs of formal training.[8] One must conclude that such employers place a high value on the forgone production that would occur with such "training." For their part, the retail trade firms do not seem to share this reluctance, for they train employees even in the face of much higher rates of voluntary turnover. This observation implies a much greater rate of return to such training investments for retail employers. Assuming that workers leave before their earnings equal their marginal productivity, these employers can pay off the investment in training and still retain a significant surplus in the classical sense. ☐

The effects of the minimum wage on farm employment: a new model

CURTIS L. GILROY

The effect of the minimum wage on employment and unemployment has received considerable attention in the empirical labor economics literature. Most analysts have tried to measure the minimum wage effects on demographic subgroups of the population, and some have investigated the effects on particular industry groups.[1] But relatively few have specifically focused on the employment effects of the minimum wage on agriculture, and their findings are generally in accord with the received neoclassical theory which hypothesizes reductions in employment as the minimum wage rises.

The following discussion reviews the empirical studies of the employment effects of the minimum wage in agriculture, and presents the results of an effort to extend and refine that research by employing a new model to test the robustness of the minimum wage effect. Results of this model, using 1967–79 data, indicate that a 10-percent increase in the agricultural minimum wage causes an employment decline of about 3 percent—the equivalent of some 45,000 farm jobs in 1979.

A review of the literature

Following the standard competitive labor market model, an increase in (or introduction of) a statutory minimum wage would cause optimizing employers to reduce the quantity of labor demanded. On the supply side, workers would offer more of their services at the higher wage. The result would be an excess supply of labor as fewer jobs are rationed among more workers.

One basic extension of this familiar comparative-static model in the recent theoretical work on the employment effects of the minimum wage is the consideration of both the covered and uncovered sectors. Recognizing that two types of jobs exist--those which are covered by the provisions of the Fair Labor Standards Act and those which are not—an increase in the Federally mandated wage would be expected to reduce employment in the covered sector. Those workers unable to find jobs there would (1) withdraw from the labor force, (2) remain unemployed in hopes of becoming reemployed in the covered sector, or (3) search for work in the uncovered sector. In the case of farmworkers, they may choose to leave agriculture altogether, and search for work in nonagricultural industries.

To the extent that agricultural workers search for work either in the uncovered sector or in nonfarm industry, the wage in the uncovered agricultural sector would fall, and the resulting employment increase would, to some extent, offset the employment loss in the covered sector. The net result depends on the rate of withdrawal of workers from the labor force, the extent to which displaced workers in the covered sector hold out in search of work there, the elasticities of demand for labor in the covered and uncovered sectors, and perceived and real employment opportunities in the nonagricultural sector. Although the relative importance of these factors is an empirical issue, the findings of the previous major studies unequivocally support the competitive hypothesis that increases in the mandated minimum have adverse employment effects. Among the findings:

- Edward Schuh found that a 10-percent increase in the minimum wage would reduce agricultural employment by 2.6 and 4.9 percent in the short and long run, respectively.[2]

Curtis L. Gilroy is chief, Personnel Policy Research Group, U.S. Army Research Institute. His full IRRA paper is entitled "Minimum Wages and Agricultural Employment: A Review of the Evidence."

- Vernon Grise concluded that if the minimum wage were set between 9 and 50 percent above the prevailing average farm wage, the decline in the hired farm work force would vary between 2 and 10 percent in the short run, and 8 and 33 percent in the long run.[3]
- Bruce Gardner estimated that the 1966 FLSA extended minimum wage coverage reduced hired farm employment by about 18 percent from what it would otherwise have been in the 1967–70 period.[4]
- Theodore Lianos found the reduction in farm employment to be between 24 and 51 percent over the years 1967–69.[5]
- Using pooled cross-section data, H.F. Gallasch, Jr. estimated that a 10-percent increase in the agricultural minimum wage would result in a decrease of 6 percent in hired farmworker employment in 1971.[6]
- Using census data, Gallasch and Gardner found that minimum wage legislation reduced hired agricultural employment about 42 percent from what it would otherwise have been in 1970.[7]
- Gardner estimated that the minimum wage reduced the number of hired farmworkers by about 115,000 or 9 percent of its 1979 level.[8]
- And, in a specialized study of seasonal cotton workers, John Trapani and J.R. Moroney found that 1966 extended FLSA coverage accounted for 65 percent of the 93,000 cotton-worker jobs eliminated between 1967 and 1969.[9]

Unfortunately, it is difficult to compare the results of these studies in terms of relative size of the measured employment effects, because each differs considerably in the period analysed, variables included, and functional form. Furthermore, it is difficult to assess how differences in the models affect the results, since most authors do not report how their findings changed as a result of changes in variables or equation specification. In addition, most studies estimate minimum wage impacts on the basis of only a few years during which the minimum wage was in effect. And in some cases, a dummy variable is used for the minimum wage.

Nonetheless, for most studies, a point employment elasticity can be derived.[10] The estimated employment elasticities are the effects of a 10-percent increase in the minimum wage, (that is, 10 times the elasticity), and range widely from −0.7 to −6.6 percent.

Extending the standard model

The time-series studies which estimate the effect of the minimum wage on agricultural employment have most often used a single equation model of the form:

$$Y = f(MW, NW, T, X_1 . . . X_n)$$

where the dependent variable Y is the measure of agricultural employment—in all cases, the level of hired farm labor employment. Independent variables include MW as the agricultural minimum wage, usually the deflated value of the Federal statutory minimum; NW as the average wage in nonagricultural industries, a measure of the opportunity wage; T as a time trend; and $X_1 . . . X_n$ as other exogenous variables, such as the cost of non-labor inputs, amount of land in use, and farm product prices. Although a business cycle variable is not explicitly included, its effect is accounted for in NW, in that NW is multiplied by 1 minus the unemployment rate to adjust for the likelihood that a farmworker may not find work at the opportunity wage.

For purposes of this analysis, a number of refinements were made to the standard model, which it was hoped would provide additional time-series evidence of the effects of the minimum wage on agricultural employment:

—A dummy variable was included in the specification to account for the sharp discontinuity of the agricultural employment series used in most studies of this type. As a result of significant changes in the sample design and collection procedure of the U.S. Department of Agriculture (USDA) Agricultural Labor Survey, there is a break in the series between 1973 and 1974.[11]

—A family labor variable was constructed to test for the substitutability of family labor for hired labor. Although earlier studies of the agricultural labor market found that various components of the farm work force were interchangeable,[12] no studies of the minimum wage have tested directly for this substitutability.

—The nonfarm wage variable was separated into its alternative nonfarm (opportunity) wage component and the unemployment (cyclical) component. Previous research has unnecessarily constrained these factors to ratio form.

—The period was limited to that during which the minimum wage was applicable to agricultural workers—1967 to the present (1979). During this 13-year period, the agricultural minimum wage increased in eight steps from $1 to $2.90 an hour. Previous authors' use of longer time series, covering many years during which there was no minimum wage in agriculture, may mask the unemployment effect of the mandated wage and make the interpretation of employment elasticities less precise.

—Quarterly data were used instead of annual observations, because employment data are collected on a quarterly basis in the Agricultural Labor Survey. As a result, three dummy variables were included in the specification to account for seasonal influences (Q_2, Q_3, and Q_4 for the second, third, and fourth quarters). Quarterly data permit us to more precisely capture changes in the minimum wage, because the change is often mandated to take effect at a time other than at the beginning of a calendar year. In addition, cyclical fluctuations are more easily discernible using quarterly, rather than annual, observations. Finally, quarterly data provide us with more degrees of freedom. For those variables for which only annual observations exist, one value is carried throughout each of the relevant quarters.

—A measure of technical change was introduced to account for innovation in agriculture.[13] This variable is the sum of expenditures on experiment station research and extension work, the former from the USDA *Inventory of Agricultural Research* and the latter from unpublished USDA data. Having experimented with lags of from one to six quarters, a two-quarter lag was chosen as performing best.

—An attempt was made to account for changes in coverage of agricultural workers under the Fair Labor Standards Act. Although coverage data are not rich, no other study has attempted to control for any changes in coverage, nor is there any mention in other studies of its potential impact. Unpublished coverage data are from the Employment Standards Administration of the U.S. Department of Labor.

—Finally, the analysis was extended to include the estimated employment effects by sex and age. Although Agricultural Labor Survey data are not disaggregated by demographic characteristics, data from the Current Population Survey permit such a breakdown.

Results of the new model

Table 1 summarizes the estimates of the effects of minimum wages on agricultural employment using various specifications of the new estimating equation. The four columns reflect differences in the functional form of the equation (linear or double-log) and the form of the important nonfarm wage variable (constrained to ratio form or unconstrained).

The rows of table 1 differ in the control variables included in addition to the minimum wage variable in explaining farm employment. For example, line 1 reports estimates of the basic equation—one which controls for season of the year, employment opportunities in the nonfarm sector, farm product prices, farm input prices, and changes in the Agricultural Labor Survey, in addition to the minimum wage (adjusted for inflation). The coefficients from these regressions have been converted to reflect the percentage change in agricultural employment as a result of a 10-percent increase in the minimum wage, that is, 10 times the employment elasticity of the minimum wage.[14]

The versions of the basic equation imply a 1.6- to 3.2-percent reduction in hired agricultural employment in response to a 10-percent increase in the minimum wage over the 1967–79 period. Unlike "basic" linear-equation estimates using annual data (not shown), the coefficients of the minimum wage variable in these similarly specified equations, which are based on quarterly data over a more relevant period, are statistically significant.

Table 1. Estimated effect of a 10-percent increase in the minimum wage on hired agricultural employment, 1967–79[1]

[In percent]

Specification	Constrained[2]		Unconstrained[2]	
	Linear	Logarithmic	Linear	Logarithmic
Basic[3]	−2.56 (2.10)	−1.57 (1.05)	−3.23 (2.42)	−2.03 (1.23)
Basic + LAND[4] + TECH[5]	−4.36 (2.49)	−4.61 (1.91)	−5.60 (3.08)	−5.34 (2.05)
Basic + LAND + TECH + FAM[6]	−4.65 (2.57)	−3.20 (2.16)	−6.27 (3.22)	−3.63 (2.29)
Basic[7]	−1.47 (2.38)	−1.69 (0.93)	−1.86 (2.70)	−2.27 (1.14)
Basic + LAND + TECH[7]	−2.48 (2.76)	−5.25 (1.83)	−2.98 (3.25)	−5.39 (1.83)
Basic + LAND + TECH + FAM[7]	−2.76 (2.79)	−3.11 (1.75)	−3.12 (3.14)	−3.22 (1.70)

[1] To control for the appreciable serial correlation evidenced by ordinary least squares equations, these estimates were calculated using generalized least squares, according to the Cochrane-Orcutt method.

[2] "Constrained" or "unconstrained" refers to the form of the important nonfarm wage variable.

[3] The basic specification includes:

—Dummy variables (Q_2, Q_3, and Q_4) to indicate the reference quarter for the data.
—A dummy variable which assumes a value of 1 for the years 1974–79 and 0 for years before 1974, to account for the methodological break in the Agricultural Labor Survey.
—*MW*—The Federally mandated agricultural minimum wage, deflated by the CPI.
—*PROD*—The index of prices received by farmers for products sold, deflated by the CPI.
—*INPUT*—The index of prices paid by farmers for nonlabor inputs, deflated by the CPI.

[4] *PLAND* is a variable representing the index of the price of agricultural land, deflated by the CPI.

[5] *TECH* is the measure of technical change, as indicated in the text.

[6] *FAM* is the ratio of the number of family workers to all agricultural workers.

[7] In addition to the variables listed in footnote 3, *COV* (the proportion of farm workers subject to the minimum wage) is also included in the specification.

NOTE: t-statistics indicated in parentheses.

Lines 2 and 3 report the results of adding various combinations of control variables to the basic equation. The size and significance of the employment elasticities appear to be largest in these more complete versions of the model. This holds true regardless of functional form. Only when a trend variable is added to the equation (not shown) are both size and statistical significance of the employment effects adversely affected. This result can be explained by the presence of trended variables—particularly technological change—already in the equation.[15]

The preferred model is that which includes all variables with sound theoretical basis (line 3). Among the four estimates, the model which includes the unconstrained version of the nonfarm wage variable makes more intuitive sense. Combining average hourly earnings and employment into one variable (common to all previous studies which measure this effect) assumes that a given change in each affects agricultural employment the same. There is no reason to assume this would be true.

The choice between functional forms is more complicated. The tendency is to prefer the logarithmic specification because variance is compressed; standards are then more stringent for levels of significance. Even so, the employment elasticities remain statistically significant at conventional levels in the more complete model (line 3). Although the elasticities are somewhat smaller in the logarithmic equations, they do provide a more conservative estimate of the minimum wage's impact. In summary, the estimates imply a reduction in employment of between 3.2 and 3.6 percent in response to a 10-percent increase in the minimum wage. This is equivalent to 41,000 to 46,000 farm jobs forgone in 1979.

Just as an increase in the minimum wage of a given number of workers raises the total wage bill, so does an increase in the number of those subject to the minimum wage provisions of the Fair Labor Standards Act. Therefore, in an attempt to account for changes in the level of FLSA coverage of agricultural workers, a variable *COV* (the proportion of farmworkers subject to minimum wage provisions of the Act) was added to the model (lines 4-6). This is preferable to combining the *level* and *coverage* into a single index, as has been done in most of the nonagricultural studies; such a multiplicative constrained relationship does not permit the estimation of the relative importance of changes in level and coverage alone.[16]

The coverage variable itself is everywhere positive, but very small and statistically insignificant (not shown). Like most studies of the nonagricultural sector, coverage effects are found to be weak. This is not altogether unexpected as the proportion of farmworkers covered is relatively low; with little variation, it has hovered about the 45-percent level throughout the 1970's. The new estimates of the minimum wage variable from this preferred model (line 6) imply an employment reduction of slightly over 3 percent, or about 41,000 jobs. These employment effects are somewhat lower than those reported in line 3, but the difference between elasticities from the linear and logarithmic equations is generally less.

Unpublished CPS employment data from the Bureau of Labor Statistics permit the estimation of minimum wage effects in agriculture by sex and age. The resulting employment elasticities for all workers and for men age 16 and over remain fairly stable (between −2.5 and −3.0 percent) and statistically significant depending upon variables included (not shown). This implies reductions in employment of between 85,000 and 100,000 for all agricultural workers, and between 65,000 and 80,000 for men.

Although less significance is exhibited in the estimates for women, striking results appear for young workers age 16 to 24. Significant disemployment effects of between 4.5 and 5.5 percent are reported. In the preferred model, a 10-percent increase in the minimum wage is estimated to result in a 5.7-percent decrease in youth employment in agriculture. Although somewhat larger, these results are consistent with those found in the literature estimating employment effects for *all* youth.[17]

Despite the consistently negative employment effects found using both the CPS and Agricultural Labor Survey data, significant conceptual and methodological differences in the surveys exist which make the elasticities derived from equations based on both data sets not strictly comparable. For example, the Agricultural Labor Survey separates hired from family agricultural workers; in the CPS there is no way to distinguish between the two. Also, the CPS is limited to persons 16 years and over, while the Agricultural Labor Survey has no age cutoff. In addition, the Agricultural Labor Survey counts all persons who do any agricultural work, including those with other jobs, but the CPS includes only those whose major activity is in agriculture. Finally, Agricultural Labor Survey data are collected four times a year on a quarterly-month basis, whereas the CPS is a monthly survey of about 65,000 households from which quarterly *averages* can be calculated. ☐

Public-sector union wage effects: a time series analysis

WILLIAM J. MOORE AND JOHN RAISIAN

Researchers have been attempting to measure the relative wage impact of unionism in the public sector for more than a decade. After surveying these research efforts, David Lewin expressed the feelings of many others when he concluded that "the 'average' wage effect of unionism in government . . . is roughly on the order of 5 percent, a much smaller impact than is popularly supposed and smaller than the average union wage impact in private industry."[1] But while this result should be comforting to those who have doubts about the propriety of transferring the process of collective bargaining to the public sector,[2] we have new time series evidence which could alter existing views on the issue.

Using longitudinal microdata from the Income Dynamics survey,[3] we developed some standardized results for a group of public employees for an extended period of time. That is, we calculated the union wage premium using the same model specification for each year for the period 1967 through 1977. (A description of our human-capital earnings model may be found in the full paper.) With these estimates, we can examine the year-to-year fluctuations in the premium to see whether there is danger in treating single-year cross-section estimates as stable indicators. Next, we pooled the annual cross-section data to estimate the overall effects of public unions for the entire period. This approach should provide us with more reliable estimates of the effects of public unions on various groups of public employees during this period. Finally, we estimated regressions for separate samples of union and nonunion public employees in order to analyze the growth rate of real wages for these types of employees. Throughout the following discussion, we present similar estimates for the economy as a whole from the same data base for comparative purposes.[4]

Annual estimates. The annual union wage premiums for public employees were calculated from ordinary least squares regressions for each year from 1967 to 1977, and were compared with union premiums for the whole economy, which we estimated earlier using an almost identical model specification.

Our results suggest that the public sector wage premium may have increased during the period 1967 to 1977, both in absolute terms, and relative to the union premium in the private sector. The average public sector union wage premium for the period 1967 to 1972 was only 8.64 percent compared to 15.87 percent for the last 5-year period observed. However, the interpretation that the public sector union wage premium has increased in recent years should be treated cautiously. Conventional F-tests revealed that the parameter estimates on the union variables are not statistically significantly different for each year. Also, the sample size virtually doubled in the latter period, perhaps accounting for the increased statistical significance of the later individual-year estimates. Finally, the public sector union premium ranged from −.12 percent to 18.32 percent over the years studied, and was substantially smaller than the wage premium for the private sector, which varied from 19.81 to 25.51 percent.

One other important point is worth noting in these cross-section results. That is, substantial variation exists in the year-to-year estimates of the union wage premium in both the public and private sectors in the United States. This finding suggests that one should be extremely cautious in drawing conclusions concerning

William J. Moore is Julian G. Lange Professor of Economics at Miami University, Oxford, Ohio. John Raisian is a senior economist in the Office of Research and Evaluation, Bureau of Labor Statistics. Their full IRRA paper is entitled "A Time Series Analysis of Union-Nonunion Relative Wage Effects in the Public Sector."

union wage effects from cross-section studies of a point in time.[5] To lessen this problem, we pooled the cross-section data to obtain an overall union wage premium for 1967–77, using a modification of the human capital-earnings model which included a Consumer Price Index deflator and a simple time trend.

The premium over time. Table 1 presents the estimated 1967–77 overall public sector union wage premium for all public employees and for some important subgroups. For comparative purposes, we also show the corresponding union wage premiums for the economy as a whole.

Our estimates of the overall wage effect of unions led to the following conclusions with respect to the influence of public unions in recent years. First, public unions have had a very substantial positive influence on the wages of their members relative to the wages of nonunion public employees, other things equal. The average public sector union wage premium for all public employees over the 1967–77 period was 12.82 percent. While this figure is substantially below the figure for private unions, 23.83 percent, it is considerably higher than the level reported in most other studies of the public sector, as noted above.[6] This is probably because our data extend to more recent years than those underlying most of the other studies, and the public sector union wage premium has been rising over time.

Second, we found that the public sector union wage premium differs significantly among various types of workers, but that the pattern of deviation is almost identical to that for the economy as a whole. In general, the premium is significantly larger for nonwhite workers (16.63 percent), southern workers (20.97 percent), and blue-collar employees (22.96 percent). Because column 3 indicates that this same pattern is present among union wage premiums for the total economy, it would appear that some basic force is in operation in union wage determination in both the public and private sectors. In an earlier paper, we attributed the relatively large union premiums for nonwhite, southern, blue-collar, and less educated workers to the attempt by unions to pursue a more-or-less standard wage for their members for reasons of equity and administrative convenience.

Table 1. Pooled estimates of union-nonunion relative wage effects in the public sector, 1967–77

Union group (1)	Percentage union wage premium	
	Public sector (2)	Total economy (3)
All union members	12.82	23.83
White	10.15	20.09
Nonwhite	16.63	30.93
South	20.97	30.94
Nonsouth	8.70	20.44
Blue-collar	22.96	30.92
White-collar	5.79	4.17

The pace of wage growth. In order to ascertain the extent of differential wage growth between union and nonunion public employees over the period, we re-estimated the modified human capital-earnings equation with a simple trend variable added for separate samples of union and nonunion employees. According to these estimates, the real hourly wage of union employees in the public sector rose by 2.044 percent annually during 1967–77, compared to only 1.543 percent for nonunion employees. However, the difference in the two growth rates was not statistically significant at the .05 level. For the economy as a whole, wages in the union sector did rise at a statistically significant higher rate (1.884 percent) than in the nonunion sector (1.118 percent).

The annual growth rate for union workers was higher in the public sector (2.044 percent) than for the total economy (1.884 percent) but the difference was not statistically significant by conventional standards. The growth rate in wages for nonunion employees was also higher in the public sector (1.543 percent) than for the economy as a whole (1.118 percent), suggesting that forces other than growth in union membership have been partially responsible for the relative gain in public sector wage rates over the period.

OUR RESULTS INDICATE that the relative wage effects of unions in the public sector may have risen in recent years. For the period 1973–77, we calculated the public sector average union wage premium to be 15.87 percent, a threefold increase over earlier cross-section estimates. For the entire 1967–77 period, the premium was 12.82 percent. While these figures are still substantially below private sector union wage premiums, it appears that the differential is narrowing. In this last regard, we found that union and nonunion employees in the public sector experienced faster rates of growth in wages than their private sector counterparts over the period. Finally, because fringe benefits are generally greater in the public sector than in the private sector, and because the threat effects of public unions may exceed those of unions in the private sector, growth in the economic influence of unions in the public sector is a phenomenon which should be watched closely in the future. ☐

[6] Part of the explanation for this is that we omitted educational and medical employees from our sample of public employees. Because it is well established that union wage premiums for public schoolteachers are relatively small (0 to 5 percent), their omission from our sample is reflected in larger union premiums.

Organizations of working women can pave the way for unions

KAREN S. KOZIARA AND PATRICE J. INSLEY

Almost two-thirds of all women who work full-time are in white-collar occupations. Relatively few of them (about 13 percent) belong to unions.[1] During the last few years, however, a number of organizations have formed outside the traditional labor movement to address working women's problems.

Between 15 and 20 major organizations of working women formed in urban areas during the last decade. About 12 of them are linked nationally. The others are local and autonomous. All are still relatively small, given the size of their potential constituencies. Few have more than a thousand members. Those members work for a number of employers in a given area, and any one firm may employ only a few members.[2] The general overarching goal of these organizations is improving employment conditions faced by working women, particularly women in low income white-collar jobs. This goal has two related dimensions. The first involves economic or "bread and butter" issues, including low wages, employment discrimination, and lack of promotional opportunities. The second dimension involves the right to be treated with dignity and to have one's work be seen as meaningful and serious and includes problems such as sexual harassment and arbitrary and demeaning treatment by supervisors. A related goal is building a firm organizational base. This involves continued organizing efforts designed to introduce working women to the idea of working together to solve shared problems.

Organizations of working women generally focus on resolving immediate problems as a way of achieving goals. The tactics used vary enormously and are tailored to the specific problem being addressed. These tactics can be classified into four general categories: information gathering, conciliation, direct action, and education.

Information gathering is both an important first step in becoming established and also an important ongoing activity for these organizations. Initially, surveys conducted among selected populations of working women help identify particular employment problems and problem employers. This information serves as a basis for program planning and as a way of letting people know of the organization's existence. Employment problems are handled on a case-by-case basis. Examples of the issues handled are failure of a firm to live up to an affirmative action plan, specific incidents of sexual harassment, low wages, and employer failure to post promotional opportunities.

Conciliation involves approaching the employer or governmental agency in an effort to resolve an identified problem. In some instances, the problem can be resolved through discussion sessions; in other instances, the employer or concerned agency is unwilling to meet with representatives of the organization or is unwilling to make any concessions. If efforts at conciliation through discussion are unsuccessful, then direct action can be used.

Direct action can take many forms. Not enough members work for any one employer to make effective use of strikes and strike threats; therefore, most forms of direct action are designed to bring the involved employer unfavorable publicity. Examples of such activities include public awards, such as a Christmas "Scrooge of the Year" award and a "Pettiest Office Procedure" award. These have the combined impact of making the organization visible, while at the same time putting pressure on the involved employer. Other forms of direct action include presentation of signed petitions, picketing, and even sit-ins.

Also government agencies can be used to pressure employers to live up to their legal obligations. This is most frequently used when the issue is affirmative action, equal employment opportunity, or age discrimination. Banks have been a major focus of this type of action because of the large numbers of low income women employed in banking. Efforts have been made by organizations of working women to have the U.S. Department of Labor's Office of Federal Contract Compliance Programs monitor affirmative action programs in the banking industry, and a number of administrative complaints have resulted. These tactics have had some success: a number of banks have made backpay settle-

The title of their full IRRA paper is "Organizing Low-Income Women in New Ways: Who, Where, and Why."

ments, four banks in Baltimore raised wages of low level bank employees, several banks and insurance companies have agreed to job posting programs, and at least one bank has instituted a major training program for clerical employees.[3]

Education and outreach are extremely important activities for working women's organizations. They are accomplished through programs, seminars, and publications and serve two major functions. First, they are a way to get visibility and to reach potential members. Getting people involved in educational programs is also an important way of increasing member commitment. It is also a service that encourages people to maintain their membership, perhaps even after a specific employer-based problem has been resolved.

The second major function performed by educational activities is to help women understand and develop ways of handling problems at work. Examples of typical subjects include skills assessment, conflict management in an office setting, equal employment opportunity law, retirement planning, assertiveness training, and career planning. Additionally, some educational programs are more general and aim at developing an understanding of common problems and solutions.

Currently, organizations of working women do not perform the functions performed by unions. They do not press for certified bargaining rights, they negotiate with employers only over limited issues, and they do not sign collective bargaining contracts. Additionally, they have relatively little contact with the labor movement.

A major reason for their independence from the labor movement is the belief that the organizing model used by unions is ineffective in organizing women in clerical occupations. There are several explanations for the labor movement's inability to effectively organize these workers. One explanation is that the labor movement has not been willing to expend the resources or develop the tactics necessary to organize successfully in these areas. A second explanation is that female clerical and service workers have not been ready to join unions.[4]

Both explanations are consistent with the emergence of working women's organizations which provide a new model for organizing female clerical workers. Some observers have described this model as "preorganizing," or creating the conditions that make union organizing viable.

In theory, the potential exists for innovative and cooperative arrangements between working women's organizations and the labor movement. There are mutual interests. Many unions are interested in organizing in new areas, and organizations of working women do not provide as broad employment protections as do collective bargaining contracts. In fact, members of one affiliate, Nine to Five in Boston, formed a local union, which joined the Service Employees International Union as Local 925.[5]

This indicates that innovative arrangements can be developed. However, the essence of innovation is doing things differently than before, and that type of organizational change is often difficult to achieve because of institutional barriers facing it. ☐

Research Summaries

Employment problems and poverty: examining the linkages

PAUL M. RYSCAVAGE

The sharp upturns in the unemployment rate in 1980 and 1981 have again focused attention on the economic consequences of unemployment and other employment problems. There is, for example, much information about the unemployed—who they are, where they live, how long they have been unemployed—but little information on the impact of unemployment on family or household income.

The generally accepted notion is that unemployment still disrupts the economic well-being of many households, although not as seriously as during the Great Depression. This is because of the increase in the number of families with two or more wage earners, and the protection now afforded workers by unemployment insurance, food stamps, public assistance, and other maintenance programs. Also a greater proportion of unemployed workers today are not the traditional primary breadwinners. In sum, there has been increasing evidence that the relationship between unemployment and economic hardship has weakened in recent decades, but this has not been quantified in any systematic way.[1]

The National Commission on Employment and Unemployment Statistics recommended in 1979 that data on unemployment, as well as other employment problems, be linked with data on income to determine the extent that job market problems cause economic hardship. The Bureau of Labor Statistics developed a data base to shed light on this question; in 1982, it issued a study which linked statistics on the labor force with statistics on family income and on the poverty status of the family.[2]

From this newly created data base for 1979—a relatively good employment year—two conclusions emerged:

- The relationship between unemployment (or other employment problems) and economic hardship was evident, but was not close. Unemployment occurred among all income levels and not all who experienced unemployment were in families with income below the poverty level.
- The linkage between unemployment (or other employment problems) and economic hardship was much tighter for some marital groups than others. For example, among women who maintained families and experienced some unemployment in 1979, the chance of living in poverty was almost 50 percent. On the other hand, for husbands who experienced some unemployment in 1979, the chance of living in poverty was only a little more than 1-in-10.

This report summarizes some of the statistics for 1979 presented in the full report. In addition, it discusses some conceptual and technical issues involved with linking labor force and income statistics, and illustrates how this new data base can be refined to produce new insights into the relationship between various employment problems and economic hardship.

Conceptual and technical issues

Labor force statistics and information on family income and poverty status were obtained from the March 1980 Current Population Survey (CPS). In March of each year, a supplemental questionnaire is used to gather information on the extent to which members of a sampled household engage in employment or job-search activities during the previous calendar year, and on the income derived from employment and other sources. This information differs from that which is collected in the monthly CPS. The monthly statistics may be regarded as a snapshot of the labor force of persons for the reference week of the survey. In this snapshot, persons are classified as employed, unemployed, or not in the labor force. The statistics from the March supplement measure the *extent* to which persons engaged in employment and unemployment activities during the previous calendar year. In this body of information, commonly referred to as the "work experience data," persons may be classified in more than one labor force category over the 12-month period.

Annual family income statistics are also collected in March and are for the previous calendar year. These statistics include wages and salaries, self-employment income, dividends, interest, rental income, public assis-

Paul M. Ryscavage is an economist in the Division of Labor Force Studies, Bureau of Labor Statistics.

tance, social security, and any other money income regularly received.[3] Not included are the value of "noncash" benefits, such as food stamps, medicaid, public housing, fringe benefits, and other items which some families receive as part of their income.[4] The poverty status of families is determined on the basis of money income. A matrix of poverty lines reflects the different consumption requirements of families based on family size, composition, age of the householder, and farm-nonfarm residence. Families with money income below a threshold amount are considered by the Federal Government to be living in poverty. In 1979, the poverty threshold for a nonfarm family of four was $7,412; for a nonfarm family of seven persons or more, it was $12,280; and for an unrelated individual age 65 or over in a farm area, $2,963.[5]

Because the annual data on work experience and family income statistics are collected at the same time and have the same reference period, it is possible to link, or cross-classify them at the micro-level. The full study linked family income and poverty status with earnings of (1) the fully employed (those who usually work 35 hours or more a week for 50 or 52 weeks); (2) the partially employed (those who usually work less than 35 hours or more a week for 50 or 52 weeks); (3) those with some part-time employment; (4) those with some unemployment; (5) those employed less than 40 weeks; and (6) nonworkers unable to find work. These linkages are discussed by the various marital and family status categories: husbands, wives, others in married-couple families; women who maintain families; others in families maintained by women; men who maintain families; others in families maintained by men; and unrelated individuals. This breakdown is useful in interpreting the linkages. However, this summary discusses only three of the linkages—those involving the relationship between family income and (1) unemployment, (2) part-time employment, and (3) low earnings among the fully employed.

The linked labor force and income statistics are, of course, subject to different interpretations regarding economic hardship because of differences in opinion over the definition of economic hardship. In both the full report and this summary, economic hardship is discussed in terms of the Federal Government's poverty guidelines, although the BLS recognizes that other definitions could have been used. The problem of interpretation becomes particularly difficult among workers who experience an employment problem, but whose family income does not fall below the poverty level. Personal inconveniences and economic disruptions obviously result, but without a universally agreed-upon definition of hardship for such workers it is difficult to evaluate the data. As a guide for data users, however, workers' family incomes have been categorized according to their proximity to the Federal Government's poverty lines.

Table 1. Relationship between duration of unemployment and family income and poverty status, 1979

[Numbers in thousands]

Family income and poverty status	With labor force experience	Without unemployment	With unemployment					
			Total	1 to 4 weeks	5 to 14 weeks	15 to 26 weeks	27 to 51 weeks	52 weeks or more
All persons age 16 and over	114,648	96,676	17,971	5,676	6,298	3,534	2,141	322

[1] Personal income for unrelated individuals.

Linked data

One of the most striking findings from the linkage of labor force and income data is that unemployment, involuntary part-time employment, low earnings, and other forms of inadequate employment are found among families at all income levels. These problems, however, were clearly most frequent among families with low incomes or little financial protection.

To put these findings in perspective, it should be noted that in 1979, the unemployment rate averaged only 5.8 percent. The linking of labor force and income data for 1980 and 1981—years in which the unemployment rate averaged more than 7 percent—would undoubtedly reveal a greater amount of labor market related economic hardship than was evident using 1979 data.

Unemployment. About 18 million persons experienced some unemployment in 1979; 30 percent of them were in families with incomes below $10,000, and 39 percent were in families with income above $20,000. (See table 1.) Slightly more than 14 percent of those with unemployment were in poor families. The prevalence of multi-earner families and the availability of unemployment insurance and welfare programs obviously cushioned the economic burden of unemployment.

Although no income class was immune to unemployment, the workers with the longest duration of unemployment were more likely to be found among lower income families. Among members of families with incomes of $20,000 or more, 10 percent of those who encountered unemployment during 1979 were jobless for 26 weeks or more; among those from families with incomes below $10,000, nearly 20 percent were unemployed for 26 weeks or more. The relationship between the duration of unemployment and income class can also be examined in terms of marital and family status. For all workers encountering unemployment, median family incomes declined as the duration of unemployment became longer—from about $18,000 for those with the shortest spells to $11,000 for those with 52 weeks or more of joblessness. (See table 2.) The extent of the downward impact on family income, however, varied depending on which member of the family was the victim of unemployment. When only the husband encountered unemployment, the duration of the spell had a sharp impact on family income. When only the wife had been unemployed, family incomes changed very little as unemployment duration lengthened. In families where only "other" members (mostly youths) experienced unemployment, income declined slightly but remained well above $20,000 regardless of the duration of unemployment. Family income was low for women who maintained families (no spouse present) and experienced unemployment, and it was even lower if their unemployment duration was more than 15 weeks.

Table 2. Relationship between duration of unemployment of selected marital and family groups and their median family incomes, 1979

Marital and family group	Weeks of unemployment				
	1 to 4	5 to 14	15 to 26	27 to 51	52 and over
Median family income of all employed persons[1]	$18,007	$16,685	$14,209	$12,366	$10,758
Husbands	19,738	17,457	14,342	10,769	([2])

[1] Personal income for unrelated individuals.

Involuntary part-time employment. Involuntary part-time employment can also cause a reduction in personal earnings and family income. Two specific causes of involuntary part-time employment are slack work and the inability to find full-time work. Of the 42.4 million persons who worked part time some weeks in 1979, about 11.2 million, or one-quarter of the total, did so involuntarily. (See table 3.) About 7.5 million were on part-time schedules because of slack work, and 3.7 million worked part time because they could not find full-time jobs. Workers who experienced some involuntary part-time employment had lower family incomes than those who worked part time voluntarily or because of strikes, bad weather, plant retooling, and other "hard-to-classify" reasons. Furthermore, a greater proportion of involuntary part-time workers were poor; their poverty rate was about 13 percent. Nevertheless, involuntary part-time employment occurs among workers from all income classes. The incidence of poverty among those with some involuntary part-time employment varies greatly by the worker's marital and family status. The incidence of poverty was 36 percent among women who maintained families, and was more than 20 percent among unrelated individuals. On the other hand, among wives and other members of married-couple families (except husbands) the proportion averaged only about 5 percent.

The following tabulation shows the incidence of poverty among persons who had some involuntary part-time work in 1979, by the worker's marital and family status:

	Percent
Total, 16 and over	13.3
Husbands	11.2
Wives	6.2
Others in married-couple families	4.7
Women who maintain families	36.5
Others in families maintained by women	22.8
Men who maintain families	17.2
Others in families maintained by men	5.9
Unrelated individuals, men	21.9
Unrelated individuals, women	26.4

Low earnings. The vast majority of the 63.4 million full-time, year-round (fully employed) workers had annual earnings above $6,000. (See table 4.) The Federal minimum wage in 1979 was $2.90 an hour, and annual earnings of $6,000 implies that hourly wages were slightly above that minimum. There were 4.8 million workers with year-round full-time jobs who earned less than $6,000 in 1979. Not surprisingly, the median income of their families was relatively low. About 1.1 million, or nearly one-fourth, were members of poor families. However, not all of the low earners were members of poor families: almost 1.2 million lived in families with incomes of $20,000 a year or more.

Husbands are seldom found among the low-earning fully employed workers whose family income is still relatively high. Wives and other members of married-couple families make up the majority of such workers. On the other hand, the majority of low-earning, fully employed workers who lived in poverty families are either husbands, women who maintain families, or unrelated individuals of both sexes.

Multiple employment problems

Although not included in the full report, experimental tabulations were created from the March 1980 CPS

Table. 4 Relationship between earnings of full-time year-round workers and family income and poverty status, 1979

[Numbers in thousands]

Family income and poverty status	Total	Personal earnings							Median personal earnings
		Under $3,000	$3,000 to $5,999	$6,000 to $7,999	$8,000 to $9,999	$10,000 to $11,999	$12,000 to $14,999	$15,000 and over	
All persons age 16 and over	63,415	1,543	3,273	5,953	6,800	7,364	9,350	29,133	$14,077
Family income:[1]									
Under $5,000	985	604	369	6	3	4	(2)	(2)	2,198
$5,000 to $9,999	4,576	296	944	1,738	1,582	10	4	2	7,230
$10,000 to $14,999	8,552	198	589	931	1,104	2,802	2,913	15	10,839
$15,000 to $19,999	10,130	146	438	997	1,135	1,131	1,648	4,634	14,221
$20,000 to $24,999	10,181	89	305	752	955	1,102	1,567	5,411	15,619
$25,000 and over	28,992	210	626	1,527	2,023	2,305	3,227	19,072	19,487
Below poverty level:									
Total	1,340	661	408	181	64	22	4	(2)	3,029
Percent	2.1	42.8	12.5	3.0	.9	.3	(2)	(2)	21.5
Below 1.25 poverty level:									
Total	2,321	761	732	436	248	103	39	(2)	$4,508
Percent	3.7	49.3	22.4	7.4	3.6	1.4	.4	(2)	32.6
Below 1.50 poverty level:									
Total	3,632	841	1,118	728	481	294	145	25	$5,482
Percent	5.7	54.5	34.2	12.2	7.1	4.0	1.6	.1	39.0

Percent	12.0	64.5	49.7	32.1	16.4	11.4	7.6	1.4	50.9
Median family income	$23,611	$7,603	$12,017	$16,419	$18,093	$18,932	$20,262	$29,357	(3)

[1] Personal income for unrelated individuals.

[2] Zero or rounds to zero.

[3] Not applicable.

Table 5. Persons with unemployment and other labor market problems, by poverty status, 1979

[Numbers in thousands]

Characteristic	Total	Number living in families below poverty level	Percent living in families below poverty level
Total	17,871	2,557	14.2
Year-round, full-time workers[1]	793	20	2.5
Nonworkers	1,927	608	31.6
All other workers	15,243	1,929	12.7
Unemployed 4 weeks or less	1,196	15	1.3
Unemployed 5 weeks or more	1,380	18	1.3
Unemployment and low hourly earnings[2]	525	92	17.5
Unemployment and involuntary part-time employment	828	21	2.5
Unemployment and employment of fewer than 40 weeks	5,835	539	9.2
Unemployment, low hourly earnings, and involuntary part-time employment	227	54	23.8
Unemployment, low hourly earnings, and employment of fewer than 40 weeks[3]	2,294	588	25.6
Unemployment, involuntary part-time employment, and employment of fewer than 40 weeks	1,886	255	13.5
Unemployment, low hourly earnings, involuntary part-time employment, and employment of fewer than 40 weeks	1,072	347	32.4

[1] Year-round full-time workers are persons who worked 50 or more weeks of the year for usually 35 hours a week or more. By definition, therefore, these persons could experience a maximum of only 2 weeks of unemployment.

[2] Low hourly earnings were defined to be $2.90 an hour or less (the minimum wage in 1979 was $2.90).

[3] Employment of fewer than 40 weeks may not represent a problem for workers who limited their workweeks because of voluntary reasons, for example, students, youths, and homemakers.

NOTE: Data may not add to total because of rounding.

showing workers with multiple employment problems. For example, workers with low earnings and unemployment were cross-classified by the poverty status of their families. Previous hardship analyses have examined various employment problems but only one problem at a time. Yet in a year's time, many workers are likely to encounter more than one employment difficulty. To single out unemployment as the primary problem responsible for a family's economic hardship may, for example, overlook a problem of low earnings caused by jobs paying minimum or sub-minimum wages.

Table 5 shows individuals who experienced some unemployment in 1979 and other possible employment problem or problems they had, and their poverty status. The majority of persons encountering unemployment in 1979 also experienced other possible employment difficulties, such as employment for less than 40 weeks, low hourly earnings, and involuntary part-time employment.[6] In fact, only a small proportion of the partially employed persons encountering unemployment during 1979 were observed as having unemployment as their sole employment problem. The incidence of poverty for these workers was negligible. Workers with the highest incidences of poverty were those who experienced such combinations of employment problems as (1) unemployment, low hourly earnings, and involuntary part-time employment; (2) unemployment, part-year employment of less than 40 weeks, and low hourly earnings; and (3) unemployment, low hourly earnings, part-year employment, and involuntary part-time employment. For workers with this last combination of problems, the incidence of poverty was more than 30 percent. Clearly then, this experimental tabulation indicates that, for many workers, unemployment is frequently associated with other employment problems. ☐

FOOTNOTES

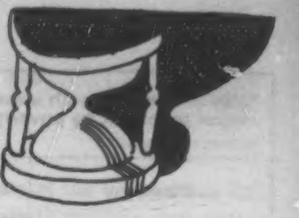
[6] For the purposes of this special tabulation, hourly earnings were derived for workers by dividing the product of weeks worked and usual weekly hours into annual earnings. Persons with hourly earnings of $2.90 (the minimum wage in 1979) or less were considered to have low hourly earnings. Many persons who worked fewer than 40 weeks in 1979 may not have had an employment problem if they limited their number of workweeks voluntarily. This is particularly true of students, youths, housewives, and others who have only a marginal attachment to the work force.

Major Agreements Expiring Next Month



This list of collective bargaining agreements expiring in July is based on contracts on file in the Bureau's Office of Wages and Industrial Relations. The list includes agreements covering 1,000 workers or more.

Employer and location	Industry	Union[1]	Number of workers
Allen-Bradley Co. (Milwaukee, Wis.)	Electrical products	Electrical Workers (UE-Ind.)	4,800
American Seating Co. (Grand Rapids, Mich.)	Furniture	Auto Workers (Ind.)	1,000
Arizona Steel Erectors Association	Construction	Iron Workers	1,500
Armstrong Rubber Co., Master Agreement (Interstate)	Rubber	Rubber Workers	3,000
Associated Garment Industries of St. Louis (Missouri)	Apparel	Ladies' Garment Workers	3,200
Associated General Contractors of America, Inc.: Mobile Chapter (Alabama and Florida)	Construction	Building and Construction Trades Council; including Teamsters (Ind.)	2,500
Association of Motion Picture and Television Producers, Inc., Basic Agreement (California)	Amusements	Theatrical Stage Employes	20,000
Association of Motion Picture and Television Producers, Inc. (California)	Amusements	Teamsters (Ind.)	2,000
Babcock and Wilcox Co., Power Generation Group (Ohio)	Fabricated metal products	Boilermakers	2,100
Columbus and Southern Ohio Electric Co.	Utilities	Electrical Workers (IBEW)	1,600
Diamond-Sunsweet, Inc. (Stockton, Calif.)	Food products	Teamsters (Ind.)	1,100

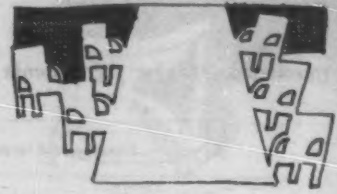
Developments in Industrial Relations



Clothing workers get new contract

Shortly before the expiration date of their agreement, the Clothing Manufacturers Association and the Clothing and Textile Workers agreed to a new 38-month agreement for 70,000 workers in the men's and boys' clothing industry. The new contract provided for a total wage increase of $1.05 an hour—25 cents an hour on October 4, 1982, 30 cents in June 1983, and 50 cents in June 1984. The automatic cost-of-living pay adjustment formula was liberalized to provide for a June 1983 adjustment of 5 cents an hour if the CPI-W rises 4.8 percent from December 1981 to December 1982, plus 1 cent for each additional .5 percent rise. An additional 5 cents will be paid in June 1984 if the index rises 5.4 percent from December 1982 to December 1983, plus 1 cent for each additional .5-percent rise.

Other terms included a 1-percent (of payroll) increase in the employer financing of pensions; establishment of paid leave for service on trial juries; and 6 hours of call-in pay (formerly 5 hours).

United Airlines settles with Machinists union

United Airlines and the Machinists negotiated a 2-year contract to lead off the union's round of bargaining with various air carriers. The accord covered mechanics and food service workers, and was the first one the parties reached in direct negotiations without a mediator in 20 years.

Company president Richard J. Ferris said that the peaceful settlement marked a "new era in labor relations" between the parties. A union official attributed the peaceful settlement to "the condition airlines are in today," referring to problems resulting from deregulation of the industry, the state of the economy, and after-effects of the 1981 strike by air traffic controllers. (The union currently represents 14,000 United employees, compared with 18,600 in 1979.) Both parties agreed that the economic condition of the industry means that it is unlikely that the union's coming settlements with the other carriers would continue the practice of following the lead settlement.

The settlement called for mechanics to receive a 10-percent pay increase, retroactive to November 1981, and an 8-percent increase in November 1982, bringing their pay rate to $15.91 an hour. Food service workers receive 8 percent and 4 percent on the respective dates.

Other terms included termination of the automatic cost-of-living pay adjustment clause (it had yielded 39 cents in increases during the previous agreement); a two-step increase in the pension rate for mechanics, bringing their rate to $29.50 a month (from $27) for each year of credited service and a two-step increase to $20.90 for food service workers; a 30-cent-an-hour increase in shift premiums; a 20-cent-an-hour increase in the premium for mechanics holding two Federal Aviation Administration licenses, bringing it to 85 cents; and improvements in medical, surgical, and dental benefits.

United gained some changes intended to improve productivity, including merging of some job classifications and changes in work schedules and hours. In 1981, United's pilots had agreed to cost-saving changes in a contract that called for pay increases of nearly 30 percent over 26 months. (See *Monthly Labor Review*, November 1981, p. 53.)

Difficulties continue in trucking industry

The Teamsters and the National Automobile Transporters Association agreed to a 3-year contract patterned on the National Master Freight Agreement the union negotiated earlier. (See *Monthly Labor Review*, April 1982, p. 64.)

Meanwhile, the union was encountering difficulties in enforcing the general freight agreement, as some of the covered companies withheld a scheduled April 1982 cost-of-living pay adjustment of 47 cents an hour, plus 25 cents to be applied to maintaining benefits. Generally, these firms said they would not pay the money because it would put them at a competitive disadvantage with companies that had withdrawn from the major employer associations prior to the "national" settlement and were now in the process of settling separately with the union. Reportedly, Trucking Management, Inc., the largest of the associations that signed the national

---

"Developments in Industrial Relations" is prepared by George Ruben of the Division of Developments in Labor-Management Relations, Bureau of Labor Statistics, and is largely based on information from secondary sources.

agreement, had only 284 firms in 1982, compared with nearly 500 in 1979.

Some of the companies covered by the master freight contract also were pressing for further concessions in negotiating the supplemental local riders to the master contract.

The difficult economic conditions in the trucking industry were indicated by the demise of Spector-Red Ball Inc., which closed its general freight hauling operations, eliminating 6,500 jobs nationwide. The company attributed the closing to intensive rate discounting resulting from the "depressed economy." The decision came despite an agreement by employees to lend the company 15 percent of their pay. Spector lost $20 million in 1981.

Elsewhere, the Teamsters and Boss Linco Lines, Inc., of Cheektowaga, N.Y., agreed to wage concessions, replacing a voluntary stock-purchase plan instituted in 1981, in which only half of the employees participated. Company president James C. Findlay said the pay concessions had been backed by 95 percent of the workers. Boss Linco, which has terminals in 14 Northeastern States, also has been operating at a loss.

AT&T guarantees jobs

American Telephone & Telegraph Co. and the Communications Workers of America agreed on a broad job and wage protection agreement for the union's members, averting a possible confrontation when the company begins its divestiture of 22 local operating units. The union started pressing for such protection after the January 1982 divestiture announcement, which was part of the settlement of an antitrust action against AT&T initiated by the Federal Government.

Under the worker protection agreement, the 235,000 union members expected to be affected by the shedding of companies are guaranteed to receive AT&T transfer benefits or those of the new firm, whichever is larger and, for 7 years after the divestiture, they are protected against loss of employment, current pay and seniority, changes in the condition of their employment, and reductions in pension, insurance, and other benefits.

CWA President Glenn Watts had pressed for broadened protections for workers because existing protections only applied to transfers within the Bell System. CWA also represents 290,000 workers in the system who will not be affected by the divestitures.

Meanwhile, AT&T was proceeding with plans to reduce the number of outside professional firms managing its two pension funds, despite the possibility that the funds would have to split into a number of funds when the divestiture occurs. AT&T said the process was being continued to put the funds in the best possible shape for the split-up of the system and that the performance of the outside managers, who received $50 million in commissions in 1981, had generally been "just average."

The two funds—one for management and the other for workers—total $36 billion. Prior to October 1980, AT&T had maintained 33 pension funds.

Marine unions seek to aid the industry

In a move to increase job opportunities and to aid the Nation's merchant marine fleet, the Seafarers and the Marine Engineers agreed on principles designed to foster closer cooperation between the two unions. One principle called for the unions to negotiate joint collective bargaining agreements, which would improve labor relations administration and cost efficiency and end jurisdictional conflicts between the unions. Union officials said this principle was impelled by the drastic decline in the merchant fleet resulting primarily from labor cost advantages enjoyed by foreign fleets. The U.S. fleet now consists of 749 vessels, with many of them in need of replacement, compared with 3,000 vessels in 1946.

The unions also agreed to joint training and upgrading programs to increase efficiency and save money; reciprocal operation of benefit funds to enable workers to preserve pension and other service credits when they change jobs, and joint legislative and political efforts to improve the condition of the industry.

The principles apply to 35,000 members of the Seafarers and 3,000 members of the Marine Engineers.

Investment plan offered at Ford

Ford announced a new investment fund for its salaried employees that will increase the money available for financing dealer and consumer purchases of company products. Under the plan, each of the 70,000 employees will be permitted to invest as little as $50 a month in Ford Motor Credit Co. floating-rate demand notes, which will pay interest one-half of a percentage point above the average yield of money market funds in the United States.

Some outside investment advisers viewed the plan as a move to bring more money into the finance subsidiary, whose commercial paper had recently been downgraded by two major credit rating services. However, Ford said that employees had been asking for such a plan and that it had been in preparation for several months.

The plan will be offered to Ford employees represented by the United Auto Workers, if the union approves.

New programs aid laid-off workers at Rockwell

The United Automobile Workers and Rockwell International Corp. announced two new programs to provide jobs for laid-off auto workers. One program gives 2,000 laid-off workers from Rockwell's automotive division preferential hiring rights at the company's aerospace plant in Columbus, Ohio. Rockwell expects to hire about 4,000 workers for the plant to build long-range combat aircraft.

UAW Secretary-Treasurer Raymond Majerus said that the program indicated Rockwell's awareness that "UAW members on layoff from its automotive plants are a very valuable resource for the company to draw upon." UAW President Douglas Fraser also applauded the hiring arrangement and said that he hoped such plans could be instituted at other aerospace firms. The UAW represents workers at Rockwell's aerospace operations, as well as at the automotive parts operations.

The other program will use a $300,000 grant from the Department of Labor to retrain workers laid off from the automobile industry for jobs at Rockwell's plants that will build the long-range aircraft.

The union indicated that the method for selecting the 400 participants in the pilot program—200 from Southwest Michigan and 200 from Ohio—would be worked out with the Department of Labor. This program is intended to provide jobs for laid-off workers, some of whom have been unemployed for many months and have exhausted all of their benefits.

Sugar workers' pay increase delayed 6 months

In Hawaii, sugar and pineapple growers sought contract concessions in separate negotiations with the International Longshoremen's and Warehousemen's union, but only the sugar growers gained cost relief.

The sugar settlement called for the deferral to July 1, 1982, of half of the 10-percent wage increase scheduled for February 1, 1982.

A union official said that the 6-month delay of half the increase would save the growers $365 per employee. Lost money would be restored to the workers if the wholesale price of sugar (19 cents a pound at the time of settlement) rises to 28 cents a pound and holds there for 30 days. Prior to the settlement, the workers earned between $6.69 and $8.62 an hour. During 1981, the sugar growers lost $83.5 million. There also was a $5 rise in the monthly rent paid by workers who live in 1,600 company-owned homes. Existing rents (for example, $35 a month for a two-bedroom unit) had not been increased since 1946.

The union agreed to establish a committee to foster increased productivity and to correct sick leave abuses. Another employer demand, for modification or elimination of incentive pay plans, led to adoption of a provision permitting local units of workers to bargain on the issue, with the international union to be given 30 days notice of any changes.

Despite the pineapple growers' contention that they were unable to compete effectively because the Hawaiian workers' minimum pay of $1,036 a month was far higher than for competitors in other countries, the 4,500 workers represented by the union won a 3-percent wage increase effective February 1, 1982, and a 2-percent increase 6 months later. Other terms of the 1-year contract included $900 annual dental insurance coverage (fomerly $600) and a change permitting nonregular workers to use paid vacation time if they are not offered work because of adverse weather.

Steel workers accept stock for benefits

Wheeling-Pittsburgh Steel Corp. agreed to exchange shares of preferred stock for cost-cutting concessions by 11,000 workers represented by the Steelworkers union. Paul Rusen, director of Steelworkers' District 23, said the union was willing to cooperate because Wheeling-Pittsburgh was making a determined effort to invest in steel and keep its plants operating. Wheeling-Pittsburgh, the Nation's eighth largest producer, reportedly has a long-term debt of $359 million, more than 30 percent of its assets.

Under the accord, scheduled to expire in November 1983, the employees agreed to defer a 15- to 47-cent wage increase scheduled to become effective in August 1982, give up a week of vacation in 1982 and in 1983, and give up 13 paid holidays from April 1982 to February 1984. In return, they will be credited with preferred stock of equal value that will pay dividends of 5 percent. The stock will become available to the employee when he or she leaves the company. Wheeling-Pittsburgh also agreed to establish a training program to prepare union members for greater participation in company operations.

A&P workers reject concessions

The Food and Commercial Workers union rejected wage and work-rule concessions A&P had proposed to help avoid further store closings. The company and union had started national negotiations on concessions in the wake of 400 store closings since last fall that had idled 15,000 members of the union. The rejected company proposal called for a 2-year wage freeze and suspension of certain scheduling restrictions, or a 10-percent pay cut so that labor costs will be "competitive with the industry average."

The union's chief bargainer said the proposal was rejected because it was "extreme" and did not offer employees "even the slightest shred of a guarantee against further reductions in staff or further store closings." A&P said that it would continue to pursue concessions in local negotiations because "we can do it better there."

General Tire to close Ohio plant

More than, 1,000 employees will lose their jobs as a result of General Tire and Rubber Co.'s announced closing of its Akron, Ohio, plant. M.G. O'Neil, chairman and president of the company, said the decision was forced by excess capacity in the tire industry, noting that 14 tire and rubber plants had closed since 1979.

United Rubber Workers President Milan Stone called the move particularly sad in view of the local's effort to save the plant. In 1979, members of Local 9 agreed to a 36-cent-an-hour wage cut and a number of changes in work rules to help General Tire accumulate funds to build a replacement for the 67 year-old facility. (See *Monthly Labor Review*, August 1979, pp. 60–61.)

The savings from the pay cut will be distributed to the workers if the parties are unable to work out a way to keep the plant open before termination of the 6-month notice period required by the 1979 agreement.

Stanford nurses' pay now highest in Nation

Registered nurses at Stanford University Medical Center in California approved a 2-year contract that, union officials said, made them the highest paid nurses in the Nation. Under the contract, a nurse with 5½ years of service in the highest of four skill categories will earn $31,283 a year, effective immediately, and $35,298 beginning March 1, 1983. Nurses in all categories received at least a 10-percent increase immediately and, in 1983, will receive a minimum of 8 percent; the maximum value of the two increases can range up to 31 percent.

Hedy Dumpel, president of the Committee for Recognition of Nursing Achievement, said the union's 1,250 members "may not be ahead in the benefit package but . . . I am sure that our salaries are the highest [in the Nation]."

The nurses' demand for greater recognition of their role in patient treatment was met by establishing a Stanford Committee on Nursing Practice that will give the nurses a direct voice in setting professional standards. The committee of four hospital representatives and four staff nurses will seek ways to better utilize nurses' skills and to promote a more cooperative approach between doctors and nurses in patient treatment.

Supreme Court rules on seniority systems

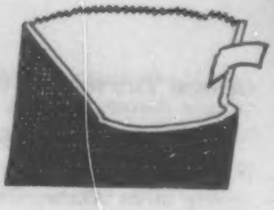
In a case involving American Tobacco Co. operations in Richmond, Va., the Supreme Court held that the immunity from legal challenge granted to bona fide worker seniority systems by the Civil Rights Act of 1964 also applies to systems adopted after passage of the act.

Writing for the five member majority, Justice White said that those who challenge a seniority system must prove that it was established with a deliberate intent to discriminate. Justice White cited Section 703 (h) of the act, which provides that "it shall not be an unlawful employment practice . . . to apply different terms, conditions, or privileges of employment pursuant to a bona fide seniority or merit system . . . provided that such differences are not the result of an intention to discriminate. . . ."

In one of the dissenting opinions, Justice Stevens backed the Fourth Circuit Court of Appeals finding that the lines of progression violated title VII of the act "because they had a disparate impact on protected employees that was not justified by any legitimate business purpose."

The case was remanded to the Fourth Circuit for reconsideration. It originated after American Tobacco Co., in 1968, combined the separate progression systems for black and white workers. John Patterson and two other black employees then filed charges with the Equal Employment Opportunity Commission alleging that American Tobacco Co. and the Tobacco Workers union had engaged in racial discrimination against them in some progression lines within the new system. Robinson's position was backed by the Federal District Court and, on appeal, by the Fourth Circuit, leading to American Tobacco's appeal to the Supreme Court.

Book Reviews



Reshaping adult education

Worklife Transitions: The Adult Learning Connection. By Paul Barton and the National Institute for Work and Learning. New York, McGraw-Hill Book Co., 1982. 196 pp. $14.95.

This book was commissioned by the National Institute for Work and Learning and is the product of an advisory committee (consisting of 29 members from business, organized labor, education, and professional associations) led by Paul Barton, vice president of the National Institute (formerly the National Manpower Institute), who pulled it all together.

Although many persons were involved in discussions and preparation of papers, the result is not the stereotypical camel produced by committee action but it does not flow as smoothly as does a good book written by one author. Nevertheless, it is replete with many provocative as well as sensible suggestions that should be studied by public policymakers, employers, unionists, educators, and others.

The book begins with an excellent foreword by Willard Wirtz, who puts everything into clear perspective. He notes that adult education serves occupational, avocational, and cultural interests through a very large and diverse system composed of private and public institutions and programs. While much is known about adult education, only dimly perceived are the shape and character of the principles that will be required in the coming years to help manage an almost complete transformation of our economic system. The important question explored throughout this volume is what is the proper role for broadly conceived adult education in a situation where the U.S. economy is undergoing an extraordinary and often painful transition from goods producing to one that is service oriented.

In 11 rather brief chapters, the authors outline the adult educational services that are available and describe the extent of participation and what needs to be done to make the system more effective for individuals and society alike. In somewhat more detail, the topics covered include the extent and characteristics of adult educational opportunity as provided by public schools, junior colleges, technical institutes, collegiate institutions, private business and industry, Federal employment and training programs, cooperative extension, professional associations, organized labor, community organizations, free universities, correspondence courses, and private instruction; who participates in such programs and why and who does not and why; who provides information concerning educational opportunities and how; what public support is available; what is offered in business, industry, and government to employees; similarly, what is being offered by trade unions, by colleges and universities, tuition aid policies and programs; the problems and prospects of longer worklife and later retirements; and an excellent final chapter which integrates these themes and spells out specific recommendations. The mere listing of these topics indicates the broad design of the book.

Several themes are emphasized and reemphasized. For one, although much is known about our educational and training system, there is no available statistical information that is collected regularly and consistently. The U.S. Department of Labor has conducted experimental and feasibility studies but to date there is no adequate informational clearinghouse. The book points out that between 38 million and 84 million people are engaged in organized learning—hardly definitive data. For another, the present system appeals more to those who have had some successful experiences in schools than those with little or minimal formal education. More white-collar than blue-collar jobholders use the adult educational system which means that better specific efforts must be made to provide information, counseling, and access for all segments of our population. Also emphasized is the fact that public employment and poverty programs have not facilitated occupational adjustments as much or as well as is required. In all cases, the authors' criticisms are made in a straightforward and reasoned manner.

The last chapter reemphasizes that information about our adult educational system, which might be much more useful to us as transition points in our lifetime, is scattered and incomplete. This, coupled with the fact that we have few qualified mentors or counselors to guide us to the right learning at the right time and from the right sponsor, means that even the present adult educational system is not as productive as it could be. What then needs to be done? Suggestions for improvement include paid educational leaves akin to sabbaticals; adult education entitlements or grants; encouraging more private investments in training; developing a national occupational change adjustment program; offering unemployed workers educational and skill improvement programs; encouraging a sincere commitment to adult education by educators; and establishing Work-Education Councils composed of employers, unions, educators, local governments, and others in every community of the Nation. Truly, an ambitious, but not impossible, agenda.

The authors have essayed a task of considerable magnitude where they attempt to prescribe the adult educational/training model for our complex society/economy of the future. They have presented the important issues relating to education and work not only for entry into work but over a lifetime of work. There is much to think about, written in a clear style, devoid of jargon and polemics.

Union membership concentration

Trade Unions in the Developed Economies. Edited by E. Owen Smith. New York, St. Martin's Press, 1981. 218 pp., bibliography. $32.50.

This slim volume discusses trade unions of seven developed countries—Australia, France, Japan, Sweden, West Germany, the United States, and the United Kingdom—and includes sections on union growth, structure, and policies. Several of the authors have had firsthand knowledge of their subject matter, for example, the chapter on Swedish trade unions. was written by T. L. Johnston, the author of an important study on collective bargaining in that country; the chapter on Australian unions was authored by two Melbourne academicians, L. Cupper and J. M. Hearn. An introduction by the editor of this book, E. Owen Smith, summarizes the contributions; Smith also contributed the chapters on the United Kingdom and West Germany.

It is not clear why the seven particular countries were selected for discussion. Each country's per capita income was probably a key factor, but several other European countries (the Netherlands, Belgium, and Austria, for example) exceed that of the United Kingdom. Presumably, the authors preferred to describe trade unions in different political and economic settings and therefore selected certain countries in order to present the reader with a variety of patterns.

There is very little new material presented in the chapter on American trade unions. The discussion on the American labor movement's failure to grow during the 1970's was well done. It is disappointing, however, that the section on union structure did not include a discussion on "intermediate bodies" within national unions. The 5-page section on trade-union policy began with Robert Hoxie's classification of unions and then explained "business unionism" and the absence of a labor party in the United States. There is little in the chapter regarding the economic impact of American unions, although some discussion was included in the introductory chapter.

If reasonably informed readers fail to learn much from this book regarding trade unions in their own countries, they will, I think, profit from the essays on the other countries. The discussion of the French trade unions' membership figures was particularly edifying because for many years this reviewer had read that there were "problems" in determining these figures. Now, at last, there is a brief explanation of the difficulties. Similarly, the chapter on Japan includes a balanced account of the strengths and weaknesses of the seniority-linked remuneration system and the lifetime employment practices.

The introductory chapter reminded us that "trade unions are very important" and that policy prescriptions involving them should be based on accurate information. Although the contributors to this volume have succeeded in supplying accurate information, this reviewer is disappointed that some effort was not made to interpret and explain the varying growth structure and policies of trade unions in the developed countries.

NOTES ON CURRENT LABOR STATISTICS

This section of the *Review* presents the principal statistical series collected and calculated by the Bureau of Labor Statistics. A brief introduction to each group of tables provides definitions, notes on the data, sources, and other material usually found in footnotes.

Readers who need additional information are invited to consult the BLS regional offices listed on the inside front cover of this issue of the *Review*. Some general notes applicable to several series are given below.

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might otherwise mask short-term movements of the statistical series. Tables containing these data are identified as "seasonally adjusted." Seasonal effects are estimated on the basis of past experience. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years.

Seasonally adjusted labor force data in tables 2-7 were revised in the March 1982 issue of the *Review* to reflect experience through 1981. The original estimates also were revised to 1970 to reflect 1980 census population controls.

Beginning in January 1980, the BLS introduced two major modifications in the seasonal adjustment methodology for labor force data. First, the data are being seasonally adjusted with a new procedure called X-11/ARIMA, which was developed at Statistics Canada as an extension of the standard X-11 method. A detailed description of the procedure appears in *The X-11 ARIMA Seasonal Adjustment Method* by Estela Bee Dagum (Statistics Canada Catalogue No. 12-564E, February 1980). The second change is that seasonal factors are now being calculated for use during the first 6 months of the year, rather than for the entire year, and then are calculated at mid-year for the July-December period. Revisions of historical data continue to be made only at the end of each calendar year.

Annual revision of the seasonally adjusted payroll data in tables 11, 14, and 16 begins with the August 1980 issue using the X-11 ARIMA seasonal adjustment methodology. New seasonal factors for productivity data in tables 30 and 31 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month to month and from quarter to quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average All Items CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100. For example, given a current hourly wage rate of $3 and a current price index number of 150, where 1967 = 100, the hourly rate expressed in 1967 dollars is $2 ($3/150 × 100 = $2). The resulting values are described as "real," "constant," or "1967" dollars.

Availability of information. Data that supplement the tables in this section are published by the Bureau of Labor Statistics in a variety of sources. Press releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule given below. The *BLS Handbook of Labor Statistics*, Bulletin 2070, provides more detailed data and greater historical coverage for most of the statistical series presented in the *Monthly Labor Review*. More information from the household and establishment surveys is provided in *Employment and Earnings*, a monthly publication of the Bureau. Historically, comparable information from the establishment survey is published in two comprehensive data books—*Employment and Earnings, United States* and *Employment and Earnings, States and Areas*, and their annual supplements. More detailed information on wages and other aspects of collective bargaining appears in the monthly periodical, *Current Wage Developments*. More detailed price information is published each month in the periodicals, the *CPI Detailed Report* and *Producer Prices and Price Indexes*.

Symbols

p = preliminary. To improve the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.

r = revised. Generally, this revision reflects the availability of later data but may also reflect other adjustments.

n.e.c. = not elsewhere classified.

Schedule of release dates for major BLS statistical series

Series	Release date	Period covered	Release date	Period covered	MLR table number
Employment situation	June 4	May	July 2	June	1-11
Producer Price index	June 11	May	July 16	June	23-27
Consumer Price index	June 22	May	July 23	June	19-22
Real earnings	June 22	May	July 23	June	12-17
Productivity and costs:					
Nonfarm business and manufacturing			July 29	2nd quarter	28-31
Major collective bargaining settlements			July 29	1st half	35-36

EMPLOYMENT DATA FROM THE HOUSEHOLD SURVEY

EMPLOYMENT DATA in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 60,000 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

Definitions

Employed persons are (1) those who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work because they were on layoff or waiting to start new jobs within the next 30 days are also counted among the unemployed. The **unemployment rate** represents the number unemployed as a percent of the civilian labor force.

The **civilian labor force** consists of all employed or unemployed persons in the civilian noninstitutional population; the **total labor force** includes military personnel. Persons **not in the labor force** are those not classified as employed or unemployed; this group includes persons retired, those engaged in their own housework, those not working while attending school, those unable to work because of long-term illness, those discouraged from seeking work because of personal or job market factors, and those who are voluntarily idle. The **noninstitutional population** comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy.

Full-time workers are those employed at least 35 hours a week; **part-time workers** are those who work fewer hours. Workers on part-time schedules for economic reasons (such as slack work, terminating or starting a job during the week, material shortages, or inability to find full-time work) are among those counted as being on full-time status, under the assumption that they would be working full time if conditions permitted. The survey classifies unemployed persons in full-time or part-time status by their reported preferences for full-time or part-time work.

Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the preceding years. These adjustments affect the comparability of historical data presented in table 1. A description of these adjustments and their effect on the various data series appear in the Explanatory Notes of *Employment and Earnings*.

Data in tables 2–7 are seasonally adjusted, based on the seasonal experience through December 1981.

1. Employment status of the noninstitutional population, 16 years and over, selected years, 1950–81

EMPLOYMENT, HOURS, AND EARNINGS DATA FROM ESTABLISHMENT SURVEYS

EMPLOYMENT, HOURS, AND EARNINGS DATA in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by 166,000 establishments representing all industries except agriculture. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

Definitions

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12th of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in manufacturing include blue-collar worker supervisors and all nonsupervisory workers closely associated with production operations. Those workers mentioned in tables 12-17 include production workers in manufacturing and mining; construction workers in construction; and nonsupervisory workers in transportation and public utilities; in wholesale and retail trade; in finance, insurance, and real estate; and in services industries. These groups account for about four-fifths of the total employment on private nonagricultural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. **Real earnings** are earnings adjusted to eliminate the effects of price change, using the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W). The **Hourly Earnings Index** is calculated from average hourly earnings data adjusted to exclude the effects of two types of changes that are unrelated to underlying wage-rate developments: fluctuations in overtime premiums in manufacturing (the only sector for which overtime data are available) and the effects of changes and seasonal factors in the proportion of workers in high-wage and low-wage industries.

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received and are different from standard or scheduled hours. **Overtime hours** represent the portion of gross average weekly hours which were in excess of regular hours and for which overtime premiums were paid.

Notes on the data

Establishment data collected by the Bureau of Labor Statistics are periodically adjusted to comprehensive counts of employment (called "benchmarks"). The latest complete adjustment was made with the release of June 1981 data, published in the August 1981 issue of the *Review*. Consequently, data published in the *Review* prior to that issue are not necessarily comparable to current data. Complete comparable historical unadjusted and seasonally adjusted data are published in a Supplement to Employment and Earnings (unadjusted data from April 1977 through March 1981 and seasonally adjusted data from January 1974 through March 1981) and in *Employment and Earnings, United States, 1909–78*, BLS Bulletin 1312–11 (for prior periods).

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20. See also *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976).

NOTE: The industry divisions of mining; construction; tobacco manufactures (a major manufacturing group, nondurable goods); transportation and public utilities; and finance, insurance, and real estate are no longer shown. This is because the seasonal component in these is small relative to the trend-cycle, or irregular components, or both, and consequently cannot be precisely separated.

UNEMPLOYMENT INSURANCE DATA

NATIONAL UNEMPLOYMENT INSURANCE DATA are compiled monthly by the Employment and Training Administration of the U.S. Department of Labor from monthly reports of unemployment insurance activity prepared by State agencies. Railroad unemployment insurance data are prepared by the U.S. Railroad Retirement Board.

Definitions

Data for **all programs** represent an unduplicated count of insured unemployment under State programs, Unemployment Compensation for Ex-Servicemen, and Unemployment Compensation for Federal Employees, and the Railroad Insurance Act.

Under both State and Federal unemployment insurance programs for civilian employees, insured workers must report the completion of at least 1 week of unemployment before they are defined as unemployed. Persons not covered by unemployment insurance (about 10 percent of the labor force) and those who have exhausted or not yet earned benefit rights are excluded from the scope of the survey. **Initial claims** are notices filed by persons in unemployment insurance programs to indicate they are out of work and wish to begin receiving compensation. A claimant who continued to be unemployed a full week is then counted in the insured unemployment figure. The **rate of insured unemployment** expresses the number of insured unemployed as a percent of the average insured employment in a 12-month period.

An **application** for benefits is filed by a railroad worker at the beginning of his first period of unemployment in a benefit year; no application is required for subsequent periods in the same year. **Number of payments** are payments made in 14-day registration periods. The **average amount of benefit payment** is an average for all compensable periods, not adjusted for recovery of overpayments or settlement of underpayments. However, **total benefits** paid have been adjusted.

[1] Initial claims and State insured unemployment include data under the program for Puerto Rican sugarcane workers.

[2] Includes interstate claims for the Virgin Islands. Excludes transition claims under State programs.

[3] Excludes data on claims and payments made jointly with other programs.

[4] Excludes data on claims and payments made jointly with State programs.

[5] Cumulative total for fiscal year (October 1-September 30). Data computed quarterly.

NOTE: Data for Puerto Rico and the Virgin Islands included. Dashes indicate data not available.

PRICE DATA

PRICE DATA are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base period (1967 = 100, unless otherwise noted).

Definitions

The **Consumer Price Index** is a monthly statistical measure of the average change in prices in a fixed market basket of goods and services. Effective with the January 1978 index, the Bureau of Labor Statistics began publishing CPI's for two groups of the population. One index, a new CPI for All Urban Consumers, covers 80 percent of the total noninstitutional population; and the other index, a revised CPI for Urban Wage Earners and Clerical Workers, covers about half the new index population. The All Urban Consumers index includes, in addition to wage earners and clerical workers, professional, managerial, and technical workers, the self-employed, short-term workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctor's and dentist's fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items is kept essentially unchanged between major revisions so that only price changes will be measured. Prices are collected from over 18,000 tenants, 24,000 retail establishments, and 18,000 housing units for property taxes in 85 urban areas across the country. All taxes directly associated with the purchase and use of items are included in the index. Because the CPI's are based on the expenditures of two population groups in 1972–73, they may not accurately reflect the experience of individual families and single persons with different buying habits.

Though the CPI is often called the "Cost-of-Living Index," it measures only price change, which is just one of several important factors affecting living costs. Area indexes do not measure differences in the level of prices among cities. They only measure the average change in prices for each area since the base period.

Producer Price Indexes measure average changes in prices received in primary markets of the United States by producers of commodities in all stages of processing. The sample used for calculating these indexes contains about 2,800 commodities and about 10,000 quotations per month selected to represent the movement of prices of all commodities produced in the manufacturing, agriculture, forestry, fishing, mining, gas and electricity, and public utilities sectors. The universe includes all commodities produced or imported for sale in commercial transactions in primary markets in the United States.

Producer Price Indexes can be organized by stage of processing or by commodity. The stage of processing structure organizes products by degree of fabrication (that is, finished goods, intermediate or semifinished goods, and crude materials). The commodity structure organizes products by similarity of end-use or material composition.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States, from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

In calculating Producer Price Indexes, price changes for the various commodities are averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1972. The detailed data are aggregated to obtain indexes for stage of processing groupings, commodity groupings, durability of product groupings, and a number of special composite groupings.

Price indexes for the output of selected SIC industries measure average price changes in commodities produced by particular industries, as defined in the *Standard Industrial Classification Manual 1972* (Washington, U.S. Office of Management and Budget, 1972). These indexes are derived from several price series, combined to match the economic activity of the specified industry and weighted by the value of shipments in the industry. They use data from comprehensive industrial censuses conducted by the U.S. Bureau of the Census and the U.S. Department of Agriculture.

Notes on the data

Beginning with the May 1978 issue of the *Review*, regional CPI's cross classified by population size, were introduced. These indexes will enable users in local areas for which an index is not published to get a better approximation of the CPI for their area by using the appropriate population size class measure for their region. The cross-classified indexes will be published bimonthly. (See table 21.)

For further details about the new and the revised indexes and a comparison of various aspects of these indexes with the old unrevised CPI, see *Facts About the Revised Consumer Price Index*, a pamphlet in the Consumer Price Index Revision 1978 series. See also *The Consumer Price Index: Concepts and Content Over the Years*, Report 517, revised edition (Bureau of Labor Statistics, May 1978).

For interarea comparisons of living costs at three hypothetical standards of living, see the family budget data published in the *Handbook of Labor Statistics, 1977*, Bulletin 1966 (Bureau of Labor Statistics, 1977), tables 122–133. Additional data and analysis on price changes are provided in the *CPI Detailed Report* and *Producer Prices and Price Indexes*, both monthly publications of the Bureau.

As of January 1976, the Wholesale Price Index (as it was then called) incorporated a revised weighting structure reflecting 1972 values of shipments. From January 1967 through December 1975, 1963 values of shipments were used as weights.

For a discussion of the general method of computing consumer, producer, and industry price indexes, see *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976), chapters 13–15. See also John F. Early, "Improving the measurement of producer price change," *Monthly Labor Review*, April 1978, pp. 7–15. For industry prices, see also Bennett R. Moss, "Industry and Sector Price Indexes," *Monthly Labor Review*, August 1965, pp. 974–82.

r = revised.

PRODUCTIVITY DATA

PRODUCTIVITY DATA are compiled by the Bureau of Labor Statistics from establishment data and from estimates of compensation and output supplied by the U.S. Department of Commerce and the Federal Reserve Board.

Definitions

Output is the constant dollar gross domestic product produced in a given period. Indexes of **output per hour of labor input**, or labor productivity, measure the value of goods and services produced per hour of labor. **Compensation per hour** includes wages and salaries of employees plus employers' contributions for social insurance and private benefit plans. The data also include an estimate of wages, salaries, and supplementary payments for the self-employed, except for nonfinancial corporations, in which there are no self-employed. **Real compensation per hour** is compensation per hour adjusted by the Consumer Price Index for All Urban Consumers.

Unit labor cost measures the labor compensation cost required to produce one unit of output and is derived by dividing compensation by output. **Unit nonlabor payments** include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from the current dollar gross domestic product and dividing by output. In these tables, **unit nonlabor costs** contain all the components of unit nonlabor payments except unit profits. **Unit profits** include corporate profits and inventory valuation adjustments per unit of output.

The **implicit price deflator** is derived by dividing the current dollar estimate of gross product by the constant dollar estimate, making the deflator, in effect, a price index for gross product of the sector reported.

The use of the term "man hours" to identify the labor component of productivity and costs, in tables 28 through 31, has been discontinued. **Hours of all persons** is now used to describe the labor input of payroll workers, self-employed persons, and unpaid family workers. **Output per all-employee hour** is now used to describe labor productivity in nonfinancial corporations where there are no self-employed.

Notes on the data

In the private business sector and the nonfarm business sector, the basis for the output measure employed in the computation of output per hour is Gross Domestic Product rather than Gross National Product. Computation of hours includes estimates of nonfarm and farm proprietor hours.

Output data are supplied by the Bureau of Economic Analysis, U.S. Department of Commerce, and the Federal Reserve Board. Quarterly manufacturing output indexes are adjusted by the Bureau of Labor Statistics to annual estimates of output (gross product originating) from the Bureau of Economic Analysis. Compensation and hours data are from the Bureau of Economic Analysis and the Bureau of Labor Statistics.

Beginning with the September 1976 issue of the *Review*, the productivity tables were revised to reflect changeover to the new series—private business sector and nonfarm business sector—which differ from the previously published total private economy and nonfarm sector in that output imputed for owner-occupied dwellings and the household and institutions sectors, as well as the statistical discrepancy, are omitted. For a detailed explanation, see J. R. Norsworthy and L. J. Fulco, "New sector definitions for productivity series," *Monthly Labor Review*, October 1976, pages 40–42.

WAGE AND COMPENSATION DATA

Data for the Employment Cost Index are reported to the Bureau of Labor Statistics by a sample of 2,000 private nonfarm establishments and 750 State and local government units selected to represent total employment in those sectors. The sample covers approximately 10,000 occupations in the private sector and about 3,700 in State and local governments.

Data on negotiated wage and benefit changes are obtained from contracts on file at the Bureau, direct contact with the parties, and secondary sources.

Definitions

The **Employment Cost Index** (ECI) is a quarterly measure of the average change in the cost of employing labor. The rate of total compensation, which comprises wages, salaries, and employer costs for employee benefits, is collected for workers performing specified tasks. Employment in each occupation is held constant over time for all series produced in the ECI, except those by region, bargaining status, and area. As a consequence, only changes in compensation are measured. Industry and occupational employment data from the 1970 Census of Population are used in deriving constant weights for the ECI. While holding total industry and occupational employment fixed, in the estimation of indexes by region, bargaining status, and area, the employment in those measures is allowed to vary over time in accord with changes in the sample. The rate of change (in percent) is available for wages and salaries, as well as for total compensation. Data are collected for the pay period including the 12th day of the survey months of March, June, September, and December. The statistics are neither annualized nor adjusted for seasonal influence.

Wages and salaries consist of earnings before payroll deductions, excluding premium pay for overtime, work on weekends and holidays, and shift differentials. Production bonuses, incentive earnings, commissions, and cost-of-living adjustments are included; nonproduction bonuses are included with other supplemental pay items in the benefits category; and payments-in-kind, free room and board, and tips are excluded. *Benefits* include supplemental pay, insurance, retirement and savings plans, and hours-related and legally required benefits.

Data on negotiated wage changes apply to private nonfarm industry collective bargaining agreements covering 1,000 workers or more. Data on compensation changes apply only to those agreements covering 5,000 workers or more. *First-year* wage or compensation changes refer to average negotiated changes for workers covered by settlements reached in the period and implemented within the first 12 months after the effective date of the agreement. *Changes over the life of the agreement* refer to all adjustments specified in the contract, expressed as an average annual rate. These measures exclude wage changes that may occur under cost-of-living adjustment (COLA) clauses, that are triggered by movements in the Consumer Price Index *Wage-rate changes* are expressed as a percent of straight-time hourly earnings: *compensation changes* are expressed as a percent of total wages and benefits.

Effective wage adjustments reflect all negotiated changes implemented in the reference period, regardless of the settlement date. They include changes from settlements reached during the period, changes deferred from contracts negotiated in an earlier period, and cost-of-living adjustments. The data also reflect contracts providing for no wage adjustment in the period. Effective adjustments and each of their components are prorated over all workers in bargaining units with at least 1,000 workers.

Notes on the data

The Employment Cost Index data series began in the fourth quarter of 1975, with the quarterly percent change in wages and salaries in the private nonfarm sector. Data on employer costs for employee benefits were included in 1980, to produce a measure of the percent change in employers' cost for employees' total compensation. State and local government units were added to the ECI coverage in 1981, providing a measure of total compensation change in the civilian nonfarm economy.

Data for the broad white-collar, blue-collar, and service worker groups, and the manufacturing, nonmanufacturing, and service industry groups are presented in the ECI. Additional occupation and industry detail are provided for the wages and salaries component of total compensation in the private nonfarm sector. For State and local government units, additional industry detail is shown for both total compensation and its wages and salaries component.

Historical indexes (June 1981 = 100) of the quarterly rates of changes presented in the ECI are also available.

For a more detailed discussion of the ECI, see chapter 25, "The Employment Cost Index," of the BLS *Handbook of Methods* (Bulletin 1910), and the *Monthly Labor Review* articles: "Employment Cost Index: a measure of change in the 'price of labor'," July 1975; "How benefits will be incorporated into the Employment Cost Index," January 1978; and "The Employment Cost Index: recent trends and expansion," May 1982.

Additional data for the ECI and other measures of wage and compensation changes appear in *Current Wage Developments*, a monthly periodical of the Bureau.

Nonmanufacturing	7.6	7.9	8.8	9.7	9.5	1.3	3.2	4.0	1.1	1.2	3.8	3.4	1.1	1.0
From settlements reached in period	3.0	2.0	3.0	3.6	2.5	.4	1.0	1.7	.5	.4	1.1	.5	.4	.1
Deferred from settlements reached in earlier period	3.2	3.7	3.0	3.5	3.8	.5	1.4	1.2	.3	.5	1.4	1.5	.4	.5
From cost-of-living clauses	1.7	2.4	3.1	2.8	3.2	.7	.8	.7	.6	.7	.7	1.2	.6	.2
Total number of workers receiving wage change (in thousands)[1]	—	—	—	—	8,848	—	—	—	—	3,855	4,701	4,364	3,205	2,713
From settlements reached in period	—	—	—	—	2,270	—	—	—	—	579	908	540	604	153
Deferred from settlements reached in earlier period	—	—	—	—	6,267	—	—	—	—	888	2,065	3,023	982	1,030
From cost-of-living clauses	—	—	—	—	4,593	—	—	—	—	2,630	2,889	2,894	2,179	1,750
Number of workers receiving no adjustments (in thousands)	—	—	—	—	145	—	—	—	—	4,937	4,062	4,426	5,596	6,176

[1] The total number of workers who received adjustments does not equal the sum of workers that received each type of adjustment, because some workers received more than one type of adjustment during the period.

WORK STOPPAGE DATA

WORK STOPPAGES include all known strikes or lockouts involving 1,000 workers or more and lasting a full shift or longer. Data are based largely on newspaper accounts and cover all workers idle one shift or more in establishments directly involved in a stoppage. They do not measure the indirect or secondary effect on other establishments whose employees are idle owing to material or service shortages.

Estimates of days idle as a percent of estimated working time measures only the impact of larger strikes (1,000 workers or more). Formerly, these estimates measured the impact of strikes involving 6 workers or more; that is, the impact of virtually *all* strikes. Due to budget stringencies, collection of data on strikes involving 6 workers or more was discontinued with the December 1981 data.

37. Work stoppages involving 1,000 workers or more, 1947 to date

Month and year		Number of stoppages		Workers involved		Days idle	
		Beginning in month or year	In effect during month or year	Beginning in month or year (in thousands)	In effect during month (in thousands)	Number (in thousands)	Percent of estimated working time

MONTHLY LABOR REVIEW

JULY 1982
VOLUME 105, NUMBER 7

Henry Lowenstern, Editor-in-Chief
Robert W. Fisher, Executive Editor

NEWARK PUBLIC LIBRARY
DEC 27 1982
U. S. GOVT. PUBS.
DEPOSITORY 376

Craig Howell and others 3 **Inflation continues to abate during the first quarter**
The rate of price increases decelerated in both the retail and primary markets, with the Consumer Price Index registering its lowest quarterly rise since 1965

Mark S. Sieling 10 **Clerical pay differences in metropolitan areas, 1961–80**
Salaries of office workers generally are higher in large urban areas and in the West and North Central region; interarea differences narrowed in 1960's, widened in 1970's

Howard N Fullerton 15 **How accurate were projections of the 1980 labor force?**
All four of the Bureau's projections were lower than the actual 1980 labor force; most of the discrepancy is linked to underestimation of participation rates of women

Max L. Carey, Kevin Kasunic 22 **Evaluating the 1980 projections of occupational employment**
Job projections prepared by BLS in 1970 proved slightly less accurate than estimates for 1965–75; classification changes limit analysis to fewer than half of 160 occupations

Neal H. Rosenthal 31 **Shortages of machinists: an evaluation of the information**
Machinists appear to be in short supply, but statistics are unreliable; employers facing shortages may raise wages, increase training, or use technological improvements

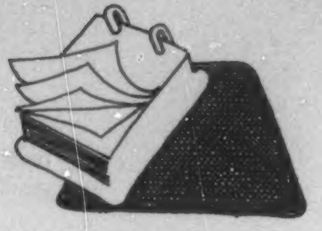
Labor Month In Review



WORK FORCE REDUCTIONS. Around the world, many firms have found it necessary to reduce the number of workers on their payrolls. The problem has caused governments, business, and workers to essay new solutions through legislation, administrative action, and collective bargaining. To assess the significance of recent developments, the International Labor Office invited a number of experts to prepare studies of current law and practice in their countries. This year, the ILO issued a volume of selected studies. The following excerpts are taken from the comparative survey of national practices by Edward Yemin, editor of the volume and head of the Labor Legislation Section of the ILO:

Change. In the industrialized market economies, a decade of growth and relative full employment in the 1960's was followed by a decade in which recurrent recessions threw large numbers of persons out of work in circumstances in which the fight against inflation muted recourse to classical Keynesian solutions for growing unemployment. At the same time, the introduction of technological innovations caused redundancies in certain industries. In addition, certain important industries in some countries went through periods of crisis and contraction due to structural problems and international competition.

Definition. By work force reduction or redundancy, we mean dismissal or long-term layoff of workers for economic, structural, or technological reasons intended either to reduce the number of workers employed or to alter the composition of the work force. Work force reductions may be effectuated by different methods from the legal point of view. The distinctions between these methods, derived from the law governing contracts of employment in the countries concerned, have become more sharply drawn in Europe and Japan, where a more formal legal view of the employment relationship has grown up, than in Canada and the United States, where the relationship still tends to be rather informal.

Comparisons. Work force reductions affect the contracts of employment of the workers concerned, involving a termination or suspension of such contracts. In European countries and in Japan, contracts of employment are either of an indefinite duration (in which case they may be terminated by giving prior notice, usually subject to rules protecting workers against unjustified dismissal), or they are for a fixed duration or specified task (in which case they terminate upon expiration of the agreed period or completion of the given task). In these countries, indefinite-duration contracts of employment tend to prevail, recourse to fixed-term contracts being limited in practice, sometimes as a result of legal restrictions on their use. In Canada and the United States, contracts of employment are generally deemed to be from day to day or even from hour to hour and may be terminated by either party at will in the absence of a contrary stipulation in the contract or in an applicable collective agreement.

In European countries, work force reductions tend to be carried out mainly through termination of the contracts of employment of the workers concerned (by dismissal, induced resignation or mutual agreement) and to a much lesser degree through nonrenewal of fixed-term contracts (few workers being employed under such contracts). Suspensions of the contract are sometimes resorted to in situations which clearly require very short interruptions of work and, when used in times of economic difficulties, are more closely associated with work-sharing arrangements such as short-time work.

In Japan, in situations where the "life-time employment" system is implemented, employers avoid as far as possible termination of their regular work force, preferring to effectuate any needed work force reduction by nonrenewal of a relatively small body of temporary workers employed under short fixed-term contracts. Where this is not sufficient, they still prefer to use other methods, including a form of temporary layoff with part pay, detachment to related companies, or induced voluntary departure. Dismissals of regular workers tend to be used only as a last resort in situations of very severe difficulty.

In Canada and the United States, work force reductions are generally carried out by layoff; however, this term is not used with conceptual precision and is employed to describe work force reductions intended to be of very brief duration and of a somewhat longer duration, and reductions that are intended to be permanent, as well as to reductions the length of which the employer is unable to foresee. Layoff may thus be intended at the outset to be either a suspension of the employment relationship or a termination; but it may also be a suspension which at some point in time becomes, either according to the terms of the applicable agreement or at the election of one of the parties, a termination. This can also occur in other countries, such as Great Britain, where a suspension of the employment relationship may be treated by the worker as a dismissal under certain circumstances.

The 214-page study, *Work force Reductions in Undertakings*: Policies and measures for the protection of redundant workers in seven industrialized market economy countries, is available from major booksellers or ILO local offices in various countries, or direct from ILO Publications, International Labour Office, CH-1211 Geneva 22, Switzerland. ☐

Inflation continues to abate during the first quarter

The rate of price increases decelerated in both the retail and primary markets, with the Consumer Price Index posting its lowest quarterly rise since 1965

CRAIG HOWELL, DAVID CALLAHAN,
AND MARY BURNS

After slowing substantially in 1981, inflation continued to decelerate in both the retail and primary markets during the first quarter of 1982. The Consumer Price Index for All Urban Consumers (CPI-U) advanced at a seasonally adjusted annual rate of increase of 1.0 percent, the lowest quarterly rise since 1965.[1] (See table 1.) The recession and a continued abundance of oil were among the principal influences pushing inflation down. The housing and auto industries, particularly hard hit by slumping demand, showed significant price decreases. Retail gasoline prices fell at a record rate, as supplies remained high.

One measure of the underlying rate of inflation—the CPI for all items less food, energy, and mortgage interest costs—increased at an annual rate of 5.7 percent in the first quarter. This was slightly more than in the preceding 3 months but was somewhat slower than the 8.0-percent rise in 1981. Replacing the present homeownership component with the future rental equivalence measure (CPI-U-X1),[2] the index would have advanced at a rate of 2.7 percent, compared with 8.5 percent in 1981.

At the primary market level, the Producer Price Index (PPI) for Finished Goods edged up at a seasonally adjusted annual rate of 0.6 percent, the slowest quarterly advance for this index since it dipped during the first quarter of 1976. The finished energy goods index fell at a rate of 18.5 percent, a drop approached only by a 14.2-percent rate of decline in the first quarter of 1976. Price increases for capital equipment and for finished consumer goods other than foods and energy both slowed to rates below 4 percent, considerably less than in other recent quarters. The index for finished consumer foods moved up moderately. Prices for intermediate goods declined slightly in the first 3 months of 1982, the first decrease since the second quarter of 1975. Because of higher raw foodstuff prices, the crude materials index rose at a rate of 1.0 percent, following sharp declines in the third and fourth quarters of 1981.

The continuing deterioration of the economy and the persistence of the highest levels of real (that is, inflation-adjusted) interest rates since the Great Depression restrained inflation in many retail and primary markets. Consumer reluctance to expand purchases of goods and services reflected such factors as fears of possible unemployment, the rising burden of interest costs on debts incurred in more inflationary times, and the difficulty of obtaining home mortgages. Some business firms canceled or postponed capital expenditures in the face of uncertain demand and their own strained profit and cash flow positions. Many companies liquidated excessive inventories because of poor

---

Craig Howell, David Callahan, and Mary Burns are economists in the Office of Prices and Living Conditions, Bureau of Labor Statistics. They were assisted by Jesse Thomas, Andrew Clem, John Wetmore, and Eddie Lamb, economists in the same office.

sales and high interest costs, or delayed rebuilding inventories until an end to the recession was more apparent. By boosting the value of the American dollar in international currency markets, high interest rates tended to price American exports out of foreign markets, while improving the competitive standing of imports in this country.

New car prices decline

Retail prices for commodities other than food and energy increased at a seasonally adjusted annual rate of 4.5 percent, a larger increase than in the fourth quarter of 1981, but somewhat below the 1981 yearly rate of 5.9 percent. (See table 2.) Prices of most commodities

Table 1. Changes in selected components of the Consumer and Producer Price Indexes, 1981–82

[1] See "Definition" and "Notes" preceding tables 19–27 of Current Labor Statistics in this *Review*.

[2] Not seasonally adjusted.

NOTE: PPI data shown above and elsewhere in this article may differ from those previously reported because PPI data through November 1981 have been revised to reflect the availability of late reports and corrections by respondents.

related to the depressed housing and automotive industries decelerated or declined. The home purchase component of the index decreased for the second consecutive quarter. Furniture price advances slowed, as the low level of new housing construction contributed to sluggish demand. Prices for textile housefurnishings also rose less than in the previous 3 months. However, price increases accelerated for many household appliances and equipment, reflecting the annual introduction of new models at higher prices.

New car prices dropped at a rate of 3.0 percent primarily because of rebates by domestic manufacturers. Despite the rebates and lower automobile finance charges, demand remained low throughout the quarter. Used car price increases slowed considerably, following large increases in the second half of 1981. Advances in tire prices continued to decelerate, reflecting the year-long slump in the market.

Retail prices of apparel other than footwear rose at an annual rate of 3.9 percent, after declining in the fourth quarter. The upturn reflected the end of discounts and higher prices for spring merchandise. Price increases for tobacco products, toilet goods, housekeeping supplies, and school books accelerated to double-digit rates.

The PPI for finished consumer goods other than foods and energy moved up at a seasonally adjusted annual rate of 3.6 percent. This represented a substantial slowdown from the 6.4-percent rate of advance at the end of 1981 and the 6.9-percent increase from December 1980 to December 1981. Unusually large rebates for some passenger cars and light motor trucks accounted for much of this deceleration. Continued rapid declines in precious metal prices were reflected in sharply lower prices for gold jewelry, silver flatware, and photographic film (which requires much silver to manufacture). Primary market prices for leather footwear, floor coverings, and televisions and radios also dropped in the first quarter. Price increases slowed markedly for soaps and detergents, books, and household furniture, while prices for sanitary paper products, tires and tubes, and glassware continued to show little or no change.

In contrast, inflation accelerated to double-digit rates in the PPI for a number of consumer products, including newspapers, periodicals, tobacco products, textile housefurnishings, cosmetics, household appliances, and prescription drugs. Each of these indexes climbed at a faster pace during the first 3 months of 1982 than in 1981 as a whole.

Capital equipment. The Producer Price Index for capital equipment rose at a seasonally adjusted annual rate of 2.1 percent, considerably less than in any other recent quarter and the slowest rate of advance since the final 3 months of 1972. (See table 3.) Most of this deceleration was caused by the downturn in the motor vehicles index, reflecting manufacturers' rebates on some new cars and light trucks; prices for heavy trucks continued to rise, although at a slower pace than in any other recent quarter. Prices for generators, textile machinery, and food products machinery turned down in the first quarter, and increases slowed for railroad equipment, printing trades machinery, agricultural machinery, metal cutting machine tools, and transformers. Construction machinery prices jumped sharply as the year began but had retreated somewhat by March, reflecting the distressed state of the construction sector.

In contrast, accelerated advances were registered for commercial furniture, photographic equipment, woodworking machinery, metal forming machine tools, and pumps and compressors. Even though demand for most kinds of capital equipment weakened markedly at the end of 1981 and into early 1982, producers of these goods felt that demand was strong enough to permit price boosts. Recent changes in tax depreciation rules were especially beneficial to commercial furniture manufacturers.

Prices for oilfield and gasfield machinery climbed at a 12.3-percent rate, twice as much as in the previous quarter, but not as fast as the 17.7-percent increase registered in 1981. Demand for these goods, which had

[1] Not seasonally adjusted.

been largely impervious to sluggishness in the overall economy over the past several years, became much weaker as 1982 began. The worldwide glut of oil and its downward pressure on prices of many kinds of petroleum products led to a marked drop in domestic oil exploration and development.

Gasoline cheaper, utilities higher

Consumer energy prices. Energy items in the CPI dropped at an annual rate of 8.0 percent in the first 3 months of 1982, the largest quarterly decrease since 1962. (See table 4.) Prices for all petroleum-based products continued the downward trend experienced since the spring of 1981. Gasoline and home heating oil supplies remained at very high levels relative to demand, leading to lower prices.

Retail gasoline prices plunged at a record rate of 27.8 percent, a dramatic contrast to the 50.4-percent rate of increase recorded for the first quarter of 1981. On an unadjusted basis, gasoline prices dropped each month without interruption from March 1981 to March 1982. The major factors pushing prices down were abundant supplies and lower demand. In addition, large supplies of low-cost Chinese gasoline were shipped to the Pacific and Gulf Coast areas. These additional supplies also reduced prices, particularly on the West Coast. Competitive pressures led to price wars in certain sections of the country, with a resultant squeeze on retailer profit margins.

Fuel oil prices decreased at an annual rate of 10.4 percent for the first quarter, the largest decline since 1965, in spite of extremely cold weather in much of the country. Factors affecting gasoline prices had a similar impact on fuel oil prices. Fuel oil prices decreased continually from March 1981 through March 1982, except when increased seasonal demand pushed prices up slightly in December and January.

In contrast to the declining trend in prices of petroleum products, consumer price increases for gas and electricity accelerated to an annual rate of 15.4 percent in the first quarter, from a 10.6-percent rate in the fourth quarter. Utility rate increases in the West and fuel adjustment increases in the North Central and South regions contributed greatly to the rise in the electricity index. Higher purchased-gas adjustments and rate increases in the South were the major factors pushing up the natural gas index.

Industrial fuels. The PPI for intermediate energy goods turned down with a 5.6-percent seasonally adjusted annual rate of decline, after advancing at a 4.2-percent rate in the fourth quarter. Continued weakening of industrial demand coupled with lower costs of crude oil resulted in price decreases for all fuels derived from petroleum.

The index for liquefied petroleum gas plummeted at a 47.3-percent annual rate; as a result, by the end of the quarter, this index was at the lowest level since the end of 1979. Prices for residual fuel, diesel fuel, and commercial jet fuel continued to fall, but less rapidly than liquefied petroleum gas prices. In marked contrast, the electric power index rose even more sharply than in the fourth quarter. Regulatory authorities granted rate increases to cover greater capital construction costs resulting from high long-term interest rates; likewise, fuel adjustment charges had an upward effect on prices in areas where coal and natural gas are used for power generation.

Crude energy. The crude energy materials index declined at a 6.5-percent annual rate in the first quarter because of sharp decreases in the index for crude petroleum (which reflects only domestic prices). Demand for crude oil continued to slide, as evidenced by the reduced volume of imports (23 percent lower than in the first quarter of 1981 and the lowest level since 1974) and the record-low rate of refinery capacity utilization (65 percent). Domestic crude oil prices fell at a rate of about 20 percent, and import prices showed similar declines. The pricing structure of the Organization of Petroleum Exporting Countries (OPEC) continued to break down, as Libya, Iran, and some other members cut their prices by more than $4 per barrel in an effort to increase their share of a shrinking market. After an emergency meeting of OPEC in March, Saudi Arabia agreed to further reduce its production levels.

Producer prices of natural gas continued to advance, but less than in other recent quarters. The slowdown was concentrated in the intrastate portion of the market, where prices had jumped sharply at the end of 1981. In contrast, somewhat larger advances occurred for interstate gas prices, reflecting the growing share of more expensive "new" gas.[3] Price increases accelerated for coal, as a weather-related surge in demand quickly affected prices because of relatively slim inventories on hand.

Food prices spurt, then dip

After showing small increases in each of the last three months of 1981, the food component of the Consumer Price Index increased rapidly in January and February, before turning down in March. The net annual rate of increase for the quarter was 3.9 percent after seasonal adjustment. The Producer Price Index for finished consumer foods showed a similar pattern during the first quarter, but rose at a net rate of 5.8 percent. The behavior of both indexes paralleled developments in the PPI category for crude foodstuffs and feedstuffs, which declined beginning in August 1981, surged in January, and then moderated in February and March.

Fresh vegetable prices showed the greatest volatility. Decreased winter acreage, the mid-January freeze in Florida, insect damage, shifts in production areas, and reduced imports from Mexico combined to lead to sharply reduced supplies as the year began. The PPI component for fresh vegetables jumped 14.7 percent in December, while the corresponding CPI measure rose 16.8 percent in January. Lettuce was particularly hard hit by whitefly damage in California and Arizona; in the CPI, prices doubled from November to January. By March, the downturn was just as sharp, with lettuce prices approaching the November level. Prices for tomatoes and many other fresh vegetables had a similar pattern. The PPI for fresh vegetables ended with a net decline for the quarter, while the corresponding CPI category ended with a net increase. Citrus fruits were also hit hard by the freeze, and retail prices for both oranges and orange juice rose substantially in January and February. Fresh orange prices had started to fall by March, though, after the extent of the damage turned out to be less than from the 1977 and 1981 freezes.

Cattle prices rose 7.8 percent; hog prices, 17.6 percent; and poultry prices, 9.7 percent over the first quarter as harsh winter weather disrupted production and marketing activity, especially in the North Central States where hog production is concentrated. In addition, hog inventories were down from year-earlier levels as farmers cut back production for 1982. Producer

[5] Not seasonally adjusted in the PPI.

prices for beef and veal, pork, and processed poultry also increased, although not as sharply. The 9.2-percent increase in producer pork prices translated into a 2.5-percent rise at the retail level.

Corn prices rose 8.7 percent in the first quarter, with virtually all of the increase occurring in January. Cold weather increased demand for feed grains. In addition, large quantities of corn were placed into the Federal grain reserve program. Wheat prices advanced 2.6 percent after seasonal adjustment. Export demand for wheat remained strong. Although cold weather did only minimal damage, the winter wheat crop was not in as good condition as last year's. Nevertheless, larger planted acreage may result in another record harvest. In contrast, milled rice prices continued to fall because of record harvests in the United States and some other rice exporting countries and improved harvests in several rice importing nations. Soybean prices also fell, as the Brazilian crop entered export markets.

Government price support programs played a key role for some farm commodities. Raw sugar prices initially rose in response to new duties and fees on imports designed to prop up domestic prices, but the target price was not achieved before prices started falling to nearly the December level.[4] Prospects of a large European sugar beet crop, large stockpiles of sugar imported before the duty was imposed, and the possibility of duty-free imports of Caribbean sugar all served to hold down prices. Because of a static support price, dairy products showed small retail price increases for four consecutive quarters despite chronic surpluses.

Rent increases ease

The services less energy component of the CPI moved up at a rate of 2.4 percent, compared with a 7.6-percent rate of increase in the previous quarter. The slowdown was largely due to a downturn in contracted mortgage interest costs, as well as slower rates of advance for a broad range of other items, including residential rent, housekeeping services, transportation services, and apparel services. The categories for medical care services and for personal and educational services continued to move up at double-digit rates, although not as fast as in other recent quarters.

Contracted mortgage interest costs declined at a rate of 6.5 percent, following a 2.8-percent rate of increase in the fourth quarter and rapid runups earlier in 1981, reflecting decreases both in house prices and in mortgage interest rates. The component for mortgage interest rates fell at a rate of 5.1 percent, in line with other long-term interest rates. The increase in the residential rent component slowed to a rate of 5.9 percent, following a 9.0-percent rate in the fourth quarter.

The transportation services category moved up at a 6.0-percent rate, considerably less than in the previous quarter. Auto finance charges moved down as some domestic car manufacturers slashed finance rates to make monthly car payments more affordable. The public transportation index (which includes fares for airlines, intercity buses and trains, and intracity mass transit) advanced at a 3.5-percent rate, somewhat less than in the preceding quarter and far less than earlier in 1981. The recent declines in fuel prices were a major factor in this slowdown.

The medical care services component of the CPI moved up at a rate of 10.4 percent, somewhat less than in other recent quarters. Charges for physicians' services moved up at a 9.7-percent rate, also less than in the fourth quarter. The index for hospital rooms rose at a rate of 12.7 percent.

Steel prices steady; gold, silver drop

The Producer Price Index for intermediate materials except foods and energy edged up at a seasonally adjusted annual rate of just 0.3 percent in the first quarter, compared with a rate of 2.4 percent in the fourth quarter. The index for durable manufacturing materials declined at a rate of 7.8 percent, an even larger decrease than at the end of 1981. Lower prices were recorded for most nonferrous metals and mill shapes, jewelers' materials, and hardwood lumber. Steel prices continued to show virtually no change, as high interest rates both weakened domestic demand and encouraged a high level of imports as the dollar rose overseas.

Prices for primary nonferrous metals continued to move down substantially, although not quite as sharply as in the fourth quarter. High interest rates and weak domestic and export markets contributed to the decreases for these metals. The end of massive support buying that had kept tin prices artificially high in late 1981 caused prices to drop severely; by March, the tin index had retreated to virtually the same level as last summer just before the runup began. Copper prices, which had declined in most months since late 1980, were further weakened by high production levels in several South American and African countries.

Gold and silver prices fell 20.3 and 18.4 percent before annualizing. Among the major reasons for these steep declines were large sales of gold by Eastern bloc countries to pay their debts, silver auctions by the General Services Administration, and the attraction of high-yielding financial investments. Prices for jewelers' materials plummeted because of falling gold prices.

Hardwood lumber prices turned down partly because of poor demand from furniture manufacturers resulting from the weak residential construction market. But prices rose for foundry and forge shop products, chiefly because of increased labor and overhead costs.

The nondurable manufacturing materials category dropped at an annual rate of 3.9 percent, following a small rise at the end of 1981. Prices for organic chemicals continued to recede because of low demand and strong competition from imports. The depressed housing and automotive industries caused a sharp downturn in the plastic resins index; prices for these materials had advanced in almost every month of 1981. An oversupply of cotton fabrics, coupled with a drop in domestic demand, meant lower prices for finished fabrics and processed yarns. Following several increases in late 1981, leather prices turned down, partly because tanners and shoe manufacturers were reluctant to rebuild inventories.

However, price increases for inorganic chemicals accelerated, with prices for caustic soda leading the way. Demand for caustic soda, particularly from the printing and publishing industry, remained relatively strong in spite of the recession. A strengthening in domestic demand for gray fabrics and synthetic fibers, especially nylon yarn, caused these prices to advance. Improved export demand led to higher prices for fats and oils.

The PPI measure for construction materials and components showed virtually no change from December to March, following generally small increases during the latter part of 1981. The poor state of construction activity permitted only marginal advances for most construction materials. Prices for a number of items, including plastic construction products, asphalt roofing, concrete products, and millwork, turned down after rising moderately in the closing months of 1981.

At the same time, the reverse was true for prices of gypsum products, building paper, and plywood. These prices advanced following declines at the end of the year, partly reflecting low supplies. Prices for refractories climbed at an unusually rapid pace; recent increases in charges for natural gas, a crucial element in the production of refractories, were the principal cause.

Among other intermediate goods, prices for machine tool parts moved up sharply during the first quarter, as orders for new machine tools sagged and producers took advantage of the consequent firming of demand for replacement parts. Glass container prices moved up substantially in February and March, after showing very little change over the preceding 8 months; the increases passed through higher natural gas costs. The index for unsupported plastic film and sheeting also rose sharply, after edging down slightly over the last half of 1981. Prices for wooden pallets, a close indicator of the state of demand in the industrial sector, continued to fall, reaching their lowest level since May 1978.

Sensitive crude material prices drop sharply

Producer prices for crude nonfood materials except energy, which tend to be highly responsive to shifts in general economic conditions, plunged at a seasonally adjusted annual rate of 40.3 percent. Prices for aluminum and copper base scrap and for iron and steel scrap continued to move down sharply in the first quarter, largely because of a lack of industrial and construction demand, weak export markets, and high interest rates. Wastepaper prices continued to fall, although not as sharply as in the fourth quarter. By the end of the first quarter, paper manufacturers had used only a portion of their wastepaper stockpiles but were purchasing additional supplies because prices were attractively low.

Crude rubber prices, which had fallen through most of 1981, continued to decline in the first quarter, largely because of persistent weakness in the automotive and tire industries. Prices for potash turned down because of an oversupply of fertilizers, excessive potash inventories, and a dwindling export market.

However, temporary short supplies of high quality cotton fibers, coupled with improved Far East and domestic demand, led to an upturn in prices for raw cotton. Prices for cattle hides also turned up as tanners began to replenish their inventories, which had been allowed to decline to unusually low levels. □

[2] For details on changing the homeownership component, see Robert Gillingham and Walter Lane, "Changing the treatment of shelter costs for homeowners in the CPI," *Monthly Labor Review*, June 1981, pp. 9–14.

[3] Under the Natural Gas Policy Act of 1978, higher prices are allowed for gas produced from wells drilled since 1978.

[4] Effective December 23, 1981, the Government raised duties and fees to bring the price of imported sugar to 19.08 cents per pound, up from 15 cents. This would eliminate the need for the Government to stockpile domestic sugar at the support price of 16.75 cents per pound. However, after an initial sharp increase in price when the duty was raised, raw sugar prices fell in March to just over the support price.

Clerical pay differentials in metropolitan areas, 1961–80

Salaries of office workers generally are higher in large urban areas and in the North Central and Western regions; interarea differences narrowed in the 1960's and widened in the 1970's

MARK S. SIELING

In 1980, salaries of office clerical workers varied widely among 52 areas included in the Bureau of Labor Statistics' area wage survey program. For example, in Davenport-Rock Island-Moline—the highest paying area—clerical pay rates averaged about 50 percent more than those in Norfolk-Virginia Beach-Portsmouth—the lowest paying area. Generally, salaries were higher in larger areas. The highest salaries were in North Central and Western areas, followed by Northeastern areas, and were lowest in Southern areas. Industry mix was an important determinant of an area's relative pay level.

The pay structure in 1980 resembled the pattern in 1961, although significant developments took place within this period. During the 1960's, area differentials gradually diminished. However, in the 1970's, the pattern reversed, and much of the growing uniformity disappeared. These contrasting developments can be attributed, in part, to the differing economic environments in the two decades. The 1960's was a period of almost uninterrupted prosperity, with only moderate rates of price increases during much of the decade; in contrast, the 1970's were characterized by both economic instability and inflationary pressures.

When the areas were ranked by the size of their pay relatives, the order of ranking in 1980 was similar to that of 1961. However, pay relatives in some areas changed substantially over the 20 years, but the changes generally reflected a cumulation of small year-to-year adjustments.

Pay levels among areas mirror the interplay of a variety of forces, ranging from nationwide economic developments to factors unique to specific locations. Moreover, the intensity of these forces may vary over time, leading to changes in interarea wage relationships. This article examines salary levels of office clerical workers in 52 metropolitan areas, highlighting current pay differences and changes in them over the past two decades.[1] In this analysis, a pay relative is defined as each area's average straight-time hourly earnings expressed as a percent of the average for all metropolitan areas combined. For example, a pay relative of 110 indicates that clerical salaries in an area are 10 percent above the national average. Pay relatives were computed by averaging earnings of selected white-collar clerical occupations in an area, using national employments as weights for each job, then dividing the resulting area average by the corresponding national average. Use of national occupational employments for weighting purposes isolates the pay relatives from the influence of area differences in occupational composition. In addition, adjustments are made to eliminate the effect of differences in the timing of individual area surveys.[2]

Mark S. Sieling is an economist in the Office of Wages and Industrial Relations, Bureau of Labor Statistics.

Patterns in 1980

Area salary levels are determined by a combination of factors. Some, such as supply and demand conditions in the labor market and occupational employment composition, are unique to an area; others, such as the general pay level of an industry or the effect of nationwide collective bargaining, are determined in a broader context. Although salary levels are unique to an area, some grouping of areas according to common characteristics can be made.

Seven of the eight areas with pay relatives of 106 or more in 1980 were located in the North Central and Western regions. (See table 1.) These areas typically had large concentrations of workers in relatively high-wage manufacturing industries, such as motor vehicles and equipment (Detroit and Toledo), aircraft and parts (Los Angeles, Seattle, and Wichita), and farm machinery (Davenport). This does not imply that the nonmanufacturing sector is unimportant in contributing to overall wage levels. Each of the five areas with overall pay levels 11 percent or more above the national average also had nonmanufacturing pay levels at least 11 percent above the national nonmanufacturing average.

Of the nine areas with pay relatives of 90 or less, seven were in the South and two were in the Northeast. The type of manufacturing industries in the area was a factor for several of these areas. For example, the textile industries are important in Chattanooga and Greenville, while leather footwear is important in Portland (Maine) and jewelry in Providence.

A relationship is also apparent between salary levels and the number of employees within a labor market. In 1980, only 11 of the 52 areas had nonagricultural employment of a million or more. Yet, four of them were among the eight areas with salaries 6 percent or more above the national average. All of the areas with salaries 10 percent or more below the national average had employment of less than a half million. A summary of this relationship was developed by calculating a Spearman rank correlation coefficient, comparing the ranking of areas by employment and salary levels.[3] The coefficient, .58, shows a positive relationship, but one that is far from a perfect correlation of 1. To illustrate that high employment does not necessarily mean higher salaries, Davenport had less than a quarter million workers in 1980, but had the highest average pay level of all the areas studied, while Boston and Minneapolis, with more than a million workers each, had average salaries 4 percent below the national average.

Salaries in Boston were also low compared to area living costs. Living costs, as measured by the BLS au-

tumn 1980 lower budget for a 4-person family,[4] are available for 22 of the areas studied. In 13 of the areas, living cost relatives (expressed as a percent of the national average for all metropolitan areas) were within 3 percentage points of the area pay relatives. Seven of the nine areas with differences greater than 3 points—Pittsburgh, Atlanta, Baltimore, Dallas, Houston, Detroit, and Los Angeles—had pay relatives that exceeded their living cost relatives; only Boston and Washington showed substantial pay disadvantages. A Spearman rank correlation coefficient of .27 confirms the lack of significant relation in the ranking of relative salary levels and local living costs in the 22 areas.[5]

Long-term trends, 1961–80

The 1980 pattern of office clerical pay relatives among areas resembled the 1961 pattern.[6] For example, in both years, Southern areas tended to be lower paying while Western areas generally were higher paying. Nevertheless, in each of the 52 areas, the pay relative changed over the 1961–80 period. Most often, the change was small, but some areas did have substantial changes. Among the larger differences, Dayton's pay relative of 106 in 1961 tied with Toledo's for seventh place; by 1980, however, Dayton's relative had decreased to 93, among the bottom third of all pay relatives. At the same time, Davenport's office pay relative rose from 103 to 122, moving from ninth to first place.

Changes in pay relatives varied by region. The pay position of all Western areas and 14 of 17 Southern areas improved by at least 1 percentage point from 1961 to 1980. By comparison, only 7 of 13 Northeastern and 6 of 16 North Central areas experienced such gains. Similarly, gains of at least 3 percentage points were proportionately more frequent in the West and South. The following tabulation shows gains and losses in pay relatives during the 1961–80 period, by area:

Percentage point change	*Northeast*	*South*	*North Central*	*West*
Gains:				
1 or 2	2	1	3	1
3 or 4	4	5	1	3
5 or 6	1	4	—	1
7 or 8	—	2	1	1
9 or more	—	2	1	—
Losses:				
9 or more	—	1	1	—
7 or 8	1	—	—	—
5 or 6	—	1	1	—
3 or 4	3	—	4	—
1 or 2	2	1	4	—

Major changes in area pay relatives can generally be traced to local developments. For example, changes in an area's industrial composition may have a marked impact on its salary levels. To illustrate, the decline of Dayton's office clerical pay relative (from 105 in 1973 to 93 in 1980) paralleled a decline in its manufacturing employment, especially in the rubber goods, household appliance, and office machinery sectors. These declines were offset to some extent by an expansion of service employment; however, the expanding service industries tended to be lower paying. In contrast, Houston's office clerical pay relative rose from 100 in 1970 to 106 in 1980. This gain can be attributed to general economic expansion, particularly in the energy field and as a site for corporate headquarters. Nonagricultural employment in Houston nearly doubled over the period.

The increase in Davenport's office clerical pay relative (from 103 in 1961 to 127 in 1980) can be traced, in part, to the combined effects of industrial composition, unionization, and inflation. A major component of Davenport's economy is farm equipment manufacturing, traditionally one of the higher paying industry groups. Most of Davenport's nonsupervisory plant and office workers in this industry are unionized; since the early 1970's, their contracts have included an uncapped cost-of-living adjustment provision. During the 1970's, the inflation rate was relatively high and, hence, these workers received relatively large wage gains through cost-of-living adjustment provisions. Although not all of Davenport's clerical work force obtained cost-of-living increases, the gains were sufficiently widespread to influence the area-wide data.

Short-term trends

Concentration on changes in area pay relatives over the 1961–80 period overlooks the contrasting patterns of change found in the 1960's and 1970's. In the 1960's, wages in the relatively low-wage Southern areas slowly approached the national average, while movement in other areas was mixed. In the 1970's, the Southern wage advances continued. In addition, pay levels in Davenport, Detroit, and most Western areas rose much faster than the average for all metropolitan areas combined. The average percent difference in pay relatives among the 52 areas narrowed from 10.0 percent in 1961 to 8.1 percent by 1969; then the pattern reversed, and the difference expanded to 10.4 percent by 1980.[7] The following tabulation shows the average percent difference among area pay relatives, from 1961 to 1980:

1961	10.0	1971	9.0
1962	9.9	1972	9.6
1963	9.3	1973	9.3
1964	9.0	1974	9.3
1965	9.0	1975	9.4
1966	8.6	1976	9.4
1967	8.8	1977	9.6
1968	8.4	1978	9.7
1969	8.1	1979	9.8
1970	8.7	1980	10.4

Average annual percentage point change	1.0	1.2	1.1	.9	.9	.9	1.1	1.1

NOTE: Changes are computed from pay relatives rounded to the nearest percent. Signs of changes are ignored.

The contrasting behavior of geographic wage differentials in the 1960's and 1970's is related to the markedly different economic conditions in those decades. The 1960's were essentially a period of economic growth. The uninterrupted economic expansion from February 1961 to December 1969, was the longest in the Nation's history. The unemployment rate—an indicator of slack in the labor market—turned downward, from 6.7 percent in 1961 to 3.5 percent in 1969. However, inflationary pressures did not surface until the latter half of the decade: annual increases in the Consumer Price Index were below 2 percent through 1965, when they began to rise, reaching 4.7 percent in 1968 and 6.1 percent in 1969. Amendments to the Fair Labor Standards Act in 1961 and 1966 raised the Federal minimum wage from $1 to $1.60 an hour; these adjustments had their greatest impact in relatively low-paying industries, and they tended to reduce wage dispersion within and among labor markets.

On the other hand, the decade of the 1970's was characterized by growing economic instability and actual or suppressed inflation. Economic recessions began in December 1969, November 1973, and January 1980. The unemployment rate rose to 8.5 percent in 1975, dropped to 5.8 percent in 1979, and then rose again to 7.1 percent in 1980. The inflation rate varied substantially: annual increases in the CPI ranged from 3.4 percent in 1971 and 1972—a period of wage and price controls—to 12.2 percent in 1974, and 13.3 percent in 1979. As in the prior decade, amendments to the Fair Labor Standards Act raised the Federal minimum wage—to $3.10 an hour in January 1980.

Year-to-year changes. For each area studied, the total change over the 1961–80 period typically reflects the cumulation of relatively small year-to-year changes. About 40 percent of the 988 annual comparisons possible over the 19 years studied showed no year-to-year change in area pay relatives. (See table 2.) A slightly larger proportion had changes of 1 percentage point. Less than 2 percent had changes of 4 percentage points or more. The average year-to-year change in pay relatives for all 52 areas was .9 percentage point.

Significantly, the tendency for small average annual changes in pay relatives appeared in each of the population size groups examined separately and in each region. Not surprisingly, the greatest stability of pay relatives was in areas with 1 million inhabitants or more—the areas which tend to have the more varied labor markets.

Annual changes in area pay relatives were small in each decade, but both the size of the average change and the frequency of relatively large change were distinctly greater in the 1970's. This finding is consistent with the tendency, already noted, for a widening of wage differences among areas in the 1970's, after a period of contraction during the 1960's.

THE WIDELY DIFFERING salary levels examined here and their behavior between 1961 and 1980 emphasize the difficulty of generalizing about the structure and trends in geographic wage differentials. Area pay rates respond to many forces that apply unequally across areas and over time. The findings of this study suggest areas of future investigation. For example, the year-to-year stability in pay relationships among areas raises the possibility of using a national survey—over short time periods—to update local pay data, thereby eliminating the need for frequent pay studies in individual localities. In addition, it would be interesting to determine if the patterns for manual jobs parallel those for white-collar jobs. Also, a study could focus on average earnings of specific occupations, rather than on average pay levels for broad employment groups within areas. ☐

FOOTNOTES

[1] This study is based on salary data from the Bureau of Labor Statistics' area wage survey program. All 52 areas surveyed annually from 1961 through 1980 are included in the analysis. (Currently, about 70 areas are surveyed.) The program provides pay estimates for office clerical; professional and technical; maintenance, toolroom, and powerplant; and material movement and custodial occupations. However, only office clerical workers are included in this analysis. The surveys of Standard Metropolitan Statistical Areas include establishments employing 50 workers or more in manufacturing; transportation, communication, and other public utilities; wholesale trade; retail trade; finance, insurance, and real estate; and selected services. In the 13 largest areas, the minimum is 100 workers in manufacturing; transportation, communication, and other public utilities; and retail trade.

[2] Pay relatives are computed annually for the metropolitan areas currently included in the area wage survey program. They are produced for four occupational groups—office clerical, electronic data processing, skilled maintenance, and unskilled plant workers. For a description of the method, as well as data for 1980, see *Wage Differences Among Metropolitan Areas, 1980*, BLS Summary 81-15, September 1981. A companion report, *Wage Differences Among Selected Areas, 1980*, BLS Summary 81-16, October 1981, provides wage comparisons for three occupational groups among 102 areas surveyed under contract to the Employment Standards Administration for use in administering the Service Contract Act.

[3] The Spearman coefficient measures the degree of association between two variables based on the ranks (or order) of the observations, rather than their actual values. A coefficient of +1 indicates complete agreement in the order of the ranks while −1 indicates completely opposite order of the ranks. A coefficient of 0 indicates the absence of any association between the variables.

[4] The lower budget was used in the comparison, because it most closely approximates expenditure levels consistent with the earnings of an office clerical worker. If the intermediate budget had been used, there would have been considerably more variation between relative wages and living costs, generally with areas in the West doing better and areas in the Northeast not doing as well. In some cases, the geographic definitions used in the budget studies did not completely correspond to those used in the salary level studies. These differences did not appreciably affect the comparison and, therefore, were ignored in the analysis. These living cost measurements reflect different consumption patterns among areas. For example, in the South a higher proportion of the meat consumed is pork than in Northern areas. The Bureau has conducted research on measuring price variations among areas assuming standard consumption patterns in all areas. The standardized consumption patterns, however, had little effect on interarea differences. See Mark K. Sherwood, "Family budgets and geographic differences in price levels," *Monthly Labor Review*, April 1975, pp. 8-15.

[5] An earlier BLS study found a relationship between area wage levels and living costs only after pay data were adjusted for differences in industry mix. See John E. Buckley, "Do area wages reflect area living costs?" *Monthly Labor Review*, November 1979, pp. 24-29.

[6] The Spearman coefficient comparing 1961 and 1980 rankings of the 52 areas is .79.

[7] Average pay differences were computed by subtracting an area's pay relative from each higher pay relative; dividing by the lower relative; totaling these differences (expressed in percent), and dividing by the number of comparisons made. For a further discussion of this technique, see Mark S. Sieling, "Interpreting pay structures through matrix application," *Monthly Labor Review*, November 1979, pp. 41-45.

How accurate were projections of the 1980 labor force?

All four Bureau of Labor Statistics projections, the first in 1965 and the last in 1976, were lower than the actual 1980 labor force; most of the discrepancy can be attributed to the underestimation of the participation rates of women

HOWARD N FULLERTON

The final step in the projection process is evaluation. The Bureau of Labor Statistics has always assessed each of its labor force projections, but only the evaluation of the 1975 estimates has been published. The 1970 projections were evaluated by Marc Rosenblum of the City University of New York.[1] Both evaluations concluded that the BLS had underestimated the number of persons in the labor force, with too many men and too few women. Rosenblum also concluded that the BLS estimate of the 1975 labor force would be too low, based on a comparison with projections by Alfred Tella and Thomas F. Dernberg and others.[2] Bureau of Labor Statistics economist Paul Ryscavage confirmed the underestimation of the BLS projections for the 1975 labor force, finding that an earlier projection, made when the program was still in the Bureau of the Census, was more accurate. He also suggested that the projections for 1980 and 1985 would be too low, primarily because of underestimation of female labor force growth. All four of the BLS projections of the 1980 labor force demonstrated the same pattern of lower than actual growth; generally the male labor force was too high and the female labor force was always too low.[3]

Trend, projected, and actual rates

The Bureau of Labor Statistics published four projections of the 1980 labor force.[4] They were general purpose projections prepared using demographic techniques. In 1965, BLS projected a 1980 labor force (including the armed forces) of 100 million; in 1970, of 101 million; in 1973, of 102 million; and, finally, in 1976, of 104 million. (See table 1.) The actual 1980 labor force was 107 million (1970 census weights).

Each estimate of the 1980 labor force overprojected the male labor force and grossly underprojected the female labor force. For example, the 1970 projection had the men's labor force at 64 million; it totaled 62 million in 1980. At the same time, the 1970 projection placed the women's labor force at 37 million; it reached 45 million in 1980.

The most difficult group to project has been women age 25 to 34. In 1965, the 1980 labor force participation rate for these women was projected to be 40.3 percent. In 1970, the rate was estimated to be 46.5 percent; in 1973, 50.2 percent; and in 1976, 57.3 percent. The rate turned out to be 65.3 percent in 1980, or 25 percentage points higher than the 1965 projection.

The next most difficult group to project was women age 35 to 44. Projection errors ranged from 15.2 percent for the 1965 estimate to 7.2 percent for the 1976 estimate.

Howard N Fullerton is a demographic statistician in the Office of Economic Growth and Employment Projections, Bureau of Labor Statistics.

The most difficult male labor force group to project was men 55 to 64. The participation rate projected in 1965 was 12.3 percent too high; however, the 1976 projection missed by only 1.1 percent. For men 25 to 34, errors ranged from 2.0 percent in the 1965 projection to −0.1 percent in the 1976 projection.

Generally, more accurate projections are made over a recent period. But, how would the projections have fared if they were adjusted for the length of the projection span? To find out, we compared historic, projected, and actual growth rates. Historic growth rates use the same number of years back as the projection is forward. For example, the 1965 projection covered 16 years (from 1964 to 1980), making 1948 the reference year for the historic growth rate. The following tabulation shows the historic and the projected and actual growth rates of the 1980 labor force:

Historic reference year	*Year projection was published*	*Growth rate*		
		Historic	*Projected*	*Actual*
1948	1965	1.25	1.73	2.14
1960	1970	1.43	1.84	2.38
1966	1973	2.00	1.68	2.28
1970	1976	1.97	1.81	2.39

Both the historic and the actual labor force growth rates increased between projections, but the projected growth changed only slightly. In effect, the improvement in the projections of the 1980 labor force was due to the application of the same growth rate to a labor force that was actually growing faster than anticipated. A simple extrapolation made on the basis of the historic growth rate would have increased the accuracy of the 1973 and 1976 projections, but not the 1965 and 1970 projections.[5]

There was a steady increase in the discrepancy between actual and projected labor force growth. The successive projected growth rates were less accurate as 1980 approached. The following tabulation presents the change between the historical growth rate and the projected growth rate (projected change), the change between the historical and actual growth rate (actual change), and the difference between the two, which is also the error in the projected growth rate (a plus sign indicates growth was projected to increase from the historical rate; minus indicates that growth was projected to decrease):

Year published	*Projected change*	*Actual change*	*Difference (error)*
1965	+0.48	+0.89	−0.41
1970	+ .41	.95	−.54
1973	−0.32	.28	−.60
1976	−0.16	.42	−.58

Participation rates of groups

How accurate were the projections for individual age-sex groups? Among individual groups, some differences between projected and actual rates leap out; for example those for women age 25 to 34 for all four projections. However, the median of all the differences between the actual and projected rates was zero—the median for men was 1.2 percentage points and for women, -6.0. This was expected because the rates for men have been dropping while those for women have been rising rapidly.

The range of differences between actual and projected participation rates for women was very large. Usual methods for detecting unusually large values, or outliers, detected none. Combining the differences for male

Table 1. The 1980 labor force and participation rates, actual and as projected in 1965, 1970, 1973, and 1976

Age	Labor force (in thousands) as projected in —				Actual 1980[2]	Participation rates as projected in —				Actual 1980[2]	Difference			
	1965	1970	1973[1]	1976[1]		1965	1970	1973[1]	1976[1]		1965	1970	1973[1]	1976[1]

[1] Middle scenarios.

[2] The 1980 labor force data are based on 1970 census weights.

NOTE: Differences with negative values were projected less than actual; those with a positive value were projected higher than actual.

and female rates does detect some outliers. The rates projected in 1965 and 1970 for women age 25 to 34 were underprojected by 25.0 and 18.8 percent. This group also had the greatest change in labor force participation over the period. One questions if a projected rise in participation of more than 25 percentage points would have been credible in 1965. The changes affecting labor force participation of women—fewer births, fewer marriages, unprecedented inflation, more education—affected women in the 25 to 44 age group the most.

Labor force composition. The projected labor force composition (age-sex structure) is of concern to those using the projections for equal opportunity purposes or for some types of market research. Table 2 shows the projected and actual distribution of the labor force. The actual and projected labor force participation rates for all four projections are illustrated in chart 1. If the projections were perfect, they would be plotted on a straight line with a slope of one (an angle of 45 degrees) going through the origin, which is the line of perfect projection.[6] When the four projections are combined, our hypothesis that the actual and projected fall on the line of perfect projection, or that the composition was correctly projected is rejected. The implication is that the composition of the labor force was poorly projected.

The bars on chart 1 show the means of the actual and projected labor force rates; if the bars were on the line of perfect fit, there would be no bias in the projection. The fit of projected against actual always goes through the point where the two means cross. If the slope of this line is different from the line of perfect fit, the composition has not been accurately projected. If the line is parallel to the line of perfect fit, then it is biased. On the other hand, if the projection is unbiased but the trend has not been accurately projected, the projection line will cross the line of perfect fit where the means cross on the line of perfect forecast.

Assumptions and realities

The Bureau of Labor Statistics' labor force projections have been based on past trends of labor force activity extended forward to particular "target" years. The extrapolated rates (modified when necessary) are then applied to population levels projected by the Bureau of the Census, producing projected labor force levels.

This general approach is essentially supply oriented. Because of this orientation, the characteristics which received the most attention from the analysts were the impact of marital status and the presence of children on the labor force activity of women and the impact of school enrollment on the participation of younger workers. For example, the analysts who prepared the 1965 and 1970 projections considered work and childrearing uncompatible roles. The analysts who prepared the 1973 projections felt that the rapid changes in participation rates would not continue; the analyst who prepared the 1976 projection allowed the rapid changes in female participation rates to continue.[7]

[1] Middle scenarios.

[2] The 1980 labor force data are based on 1970 census weights.

It will be helpful to review the changes in marital status, presence of children, and educational attainment that have occurred since 1965. While such a discussion will not explain the projection errors, it will indicate whether the underlying supply assumptions of the four BLS projections were met.[8]

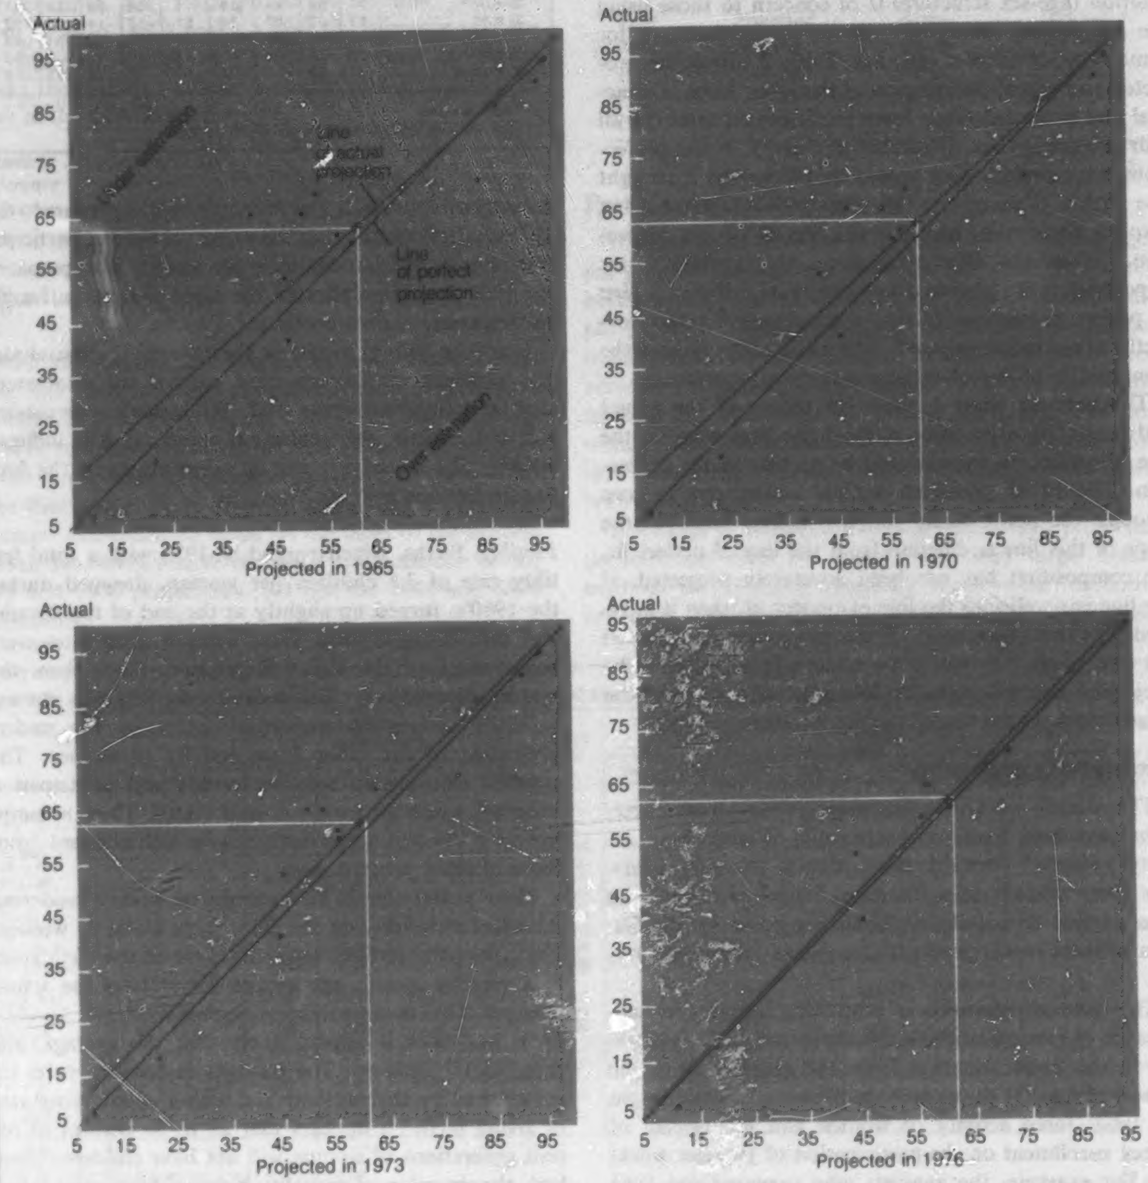
Fertility. Births, which peaked in 1958 with a total fertility rate of 3.8 children per woman, dropped during the 1960's, turned up slightly at the end of the decade, and then dropped until 1976, when fertility rates were below those of the Great Depression. Since then, the rate has risen slowly. The decline in fertility was not anticipated and is an important factor in the underprojection of the labor force activity of women. The negative relationship between fertility and participation lessened, which also was not anticipated. These assumptions by the BLS projectionists were not different from those of other projectionists.

Three points should be remembered when considering the effect of fertility on the labor force status of women. First, the total fertility rate—the sum of the birth rates in a year by specific age groups—overstates the actual changes. That is, no cohort of women averaged 3.8 children, nor does it appear likely that the average will drop to 1.7 children. The changes in fertility were accomplished by shifting both the timing of marrying and of giving birth.[9] It appears that 20 to 30 percent of recent generations of women will not have children.[10] Second, the direction of causality between births and labor force activity is ambiguous. Both are affected by similar factors, such as education, inflation, and the changing social expectation. Increased labor force participation may induce tastes that are incompatible with motherhood. Third, there is a direct effect on labor force participation in that childbirth generally results in the mother withdrawing from the labor force, even if for a short time.

Marital status. The changing marital status of the population also affected the growth of the labor force. Not as many married women lived in traditional (spouse present) households.

There was a small, 3-percent annual change in the proportion of married women over the 15-year-period, but if applied to the 87 million women in 1980 who

Chart 1. Labor force participation rates for 1980, actual and projected in 1965, 1970, 1973, and 1976



were 16 or older, it amounts to almost 3 million fewer married women. This shift in the proportion of married women resulted in a greater number of women in the labor force, and was reinforced by the increase in the participation rates of married women. The drop in the proportion of married women reflects the "marriage squeeze," the increased divorce rate, and the postponement of marriage. (Marriage squeeze refers to the joint effect of increasing births and the marriage of women to men about 2 years older. About 20 years after the period of increasing births, there would be fewer men than women of marriageable age.) These factors also lowered the birth rate and the proportion of women with young children.

Parental status. As the proportion of women with young children dropped (as the lower fertility rates implied), their share of the labor force rose. The 1965 projection did not assume growth in the labor force participation of mothers of young children and also did not expect births to drop to such a low level. The 1970 projection also did not explicitly include these assumptions. The 1973 and the 1976 projections attempted to project the number of women with young children by using the current population projections of births. However, both projections overestimated the proportion of mothers of young children and, thus, underprojected the growth of the labor force. The implicit assumption in each projection of the size of the negative relationship between the presence of young children and the labor force activity of their mothers was another factor in the underprojection of the labor force activity of women with young children. In addition, it is more difficult to project marital and parental status than labor force status.

Education. American workers steadily increased their years of formal schooling between 1965 and 1980. This behavior was explicitly modeled in the 1965 and 1970 projections and implicitly assumed in the 1973 and 1976 projections. As education increases, the labor force participation of women also increases.[11]

Inflation. Price changes affect many aspects of economic and social life and, thus, would be expected to have some effect upon labor force activity. Certainly, the projectionists made no explicit assumptions about the rate of price increase, but its effect on participation has been explored by many.[12] Valerie K. Oppenheimer suggested that wives participate more actively in the labor force to maintain family spending because real earnings of the husband remain constant while the family life-cycle requires increasing real income. James E. Duggan found that increased participation of wives is partly caused by the uncertainty engendered by rapid rates of price change. Thus, the rapid price changes of recent years probably contributed to the larger than anticipated labor force growth.

To summarize the assumed versus actual experiences affecting the 1980 labor force, fertility was lower than anticipated, resulting in higher female participation than projected; the lesser rate of withdrawal by women to tend young children also meant higher participation. The proportion of women living with their spouses dropped, which would tend to make female participation rise. We cannot evaluate how well this was anticipated in 1965 because of data limitations; since 1970, it has not been formally a part of the "model." The number of years of schooling completed rose and, for women, so did participation.[13] Finally, the unprecedented rise in inflation was not anticipated and probably resulted in more wives actively seeking work.

Comparison with other projections

In 1977, Data Resources, Inc., projected that the civilian labor force would increase to 102,500,000 in 1980, or 1.95 percent per year.[14] By comparison, in 1976, BLS projected a civilian labor force of 101,600,000 in 1980, a growth rate of 1.86 percent per year. The 1980 labor force was 104,700,000, a 2.46-percent growth rate.

Data Resources projection had a somewhat smaller error (–.51 percent) than the BLS projection (–.60 percent), and, of course, was made a year later. Table 3 compares the projected civilian labor force rates of Data Resources and BLS.

Overall, BLS did slightly better at projecting 1980 participation rates than did Data Resources; the mean of the absolute values of the deviations is 2.0 for BLS and 2.5 for Data Resources. Both were good at projecting male rates, but Data Resources was superior at projecting female rates. Interestingly, Data Resources was

Table 3. Comparison of Data Resources and BLS projections of 1980 civilian labor force participation rates

[In percent]

Age	Projection		Actual	Errors	
	Data Resources	BLS		Data Resources	BLS
Women:					
16 to 17	45.3	43.1	43.8	1.5	–0.7
18 to 19	62.5	60.0	62.1	.4	–2.1
20 to 24	69.7	68.4	69.0	–.7	–.6
25 to 34	62.4	57.4	65.4	–3.0	–8.0
35 to 44	60.1	58.3	65.5	–5.4	–7.2
45 to 54	55.7	57.1	59.9	–4.2	–2.8
Men:					
16 to 17	50.3	50.6	50.1	.2	.5
18 to 19	66.5	71.5	71.5	–5.0	0
20 to 24	81.6	84.2	86.0	–4.4	–1.8
25 to 34	93.1	95.2	95.3	–2.2	–.1
35 to 44	94.0	95.5	95.5	–1.5	0
45 to 54	89.9	91.2	91.2	–1.3	0

NOTE: These rates do not reflect any adjustment for the 1980 census.

much better at projecting rates for women age 25 to 34 (estimating rates for this age group has always been difficult for BLS). Also, Data Resources' worst projection, that for women age 35 to 44 years, was still better than any of the BLS projection rates for women. Among women, only for those age 16 and 17, and 45 to 54, did BLS have lower projection errors than Data Resources. Among men, the Data Resources projection was better than the BLS projection only for those 16 to 17 years. The feat of projecting some of the rates for men exactly should be discounted, indeed the Data Resources error of 0.2 percentage point should be considered equivalent to an exact projection. In general, the superior projection made by one projecting group for a sex was offset by the errors made in projecting rates for the other group.

Guidelines for users

The labor force projections are prepared for a variety of users. Within the Bureau of Labor Statistics, they are an input into the employment, output, and occupational projections; they are also used in employment and training policy development, in market research, in equal employment opportunity work, and by many States as inputs into State labor force and population projections.[15] It is not clear what level of accuracy is satisfactory—we presented several measures of errors; the user of the projections should select the measure most relevant to the specific application.

There are occasions when the levels or accuracy described here are not sufficient (for example, when the range of uncertainty exceeds the usual levels of unemployment).

If the projections are to be used in simulations concerning unemployment, they should be used with great caution. Nathan Keyfitz commented that the errors in population projections over a 20-year span are sufficiently wide as to limit their usefulness; labor force projections are even more constrained.[16]

Most users tolerate a lower accuracy in long-run than in short-run projections because of their different purposes, and because decisions based on long-run projections can be revised or shifted over time. For example, the decision to build or to not build a sewage treatment facility does not depend on the accuracy of the population projected for a locality, but rather on the likelihood of the population exceeding a specific number. If the facility is built and the population does exceed the threshold number, then the projection was useful even if it was not accurate.[17]

If the future labor force could be determined with no error, it would not be necessary to revise projections. Four comments should be helpful. First, at the time each of the four projections was made the assumptions about the future of the labor force were reasonable. Second, none of the projections has any turning points; it is quite likely that some of the labor force series will indeed change direction. Third, as Henri Theil points out, projections must at some place in their structure hold change constant, whether it is the level of net migration or the rate of change; this has the effect of underestimating the amount of change.[18] Further Jacob Mincer and Victor Zarnowitz say that it is harder to project a rising level of activity.[19] These tendencies results in overestimate of the level of men's labor force activity—and underestimate of the activity of women. The relative sizes of the two components of the labor force is more poorly projected. ☐

Johnston, "Labor Force Projections for 1970–80," February 1965, p. 129–39 (reprinted as Special Labor Force Report 49); Sophia Cooper Travis, "The U.S. labor force; projections to 1985," May 1970, pp. 3–12 (reprinted as Special Labor Force Report 119); Denis F. Johnston, "The U.S. labor force: projections to 1990," July 1973, pp. 3–13 (reprinted as Special Labor Force Report 156); and Howard N Fullerton and P.O. Flaim, "New labor force projections to 1990," December 1976, pp. 3–13 (reprinted as Special Labor Force Report 197).

[5] Michael A. Stoto, "The Accuracy of Population Projections" (Laxenburg, Austria, International Institute for Applied Systems Analysis, 1979). Stoto also found that over the first 10 years of a population projection, the naive extrapolation method was more accurate than other methods.

[6] For more information on this type of comparison, see Henri Theil, *Economic Forecasts and Policy* (Amsterdam, North-Holland Publishing Co., 1965), and *Applied Econometric Forecasting* (Chicago, Rand-McNally and Co., 1966).

[7] The 1965, 1973, and 1976 projections each looked at specific population groups (for example, mothers of young children), thus, it should be possible to partition the error in the labor force projection into that due to the size of a specific group and that due to the projection of labor force rate. However, the archives for the labor force projections are not available, and we can only look at the overall error for the major group.

[8] Only 1965 projections considered the effects of a drop in the unemployment rate (to 3 percent); it concluded that for every 3 jobs created 2 would be filled by the unemployed and one by new labor force entrants. Attempts to prove the effect symmetric were unsuccessful, so it is not possible to conclude what effect the higher unemployment rate would have had on the labor force.

Evaluating the 1980 projections of occupational employment

Job projections prepared by BLS in 1970 proved slightly less accurate than estimates for 1965-75; classification changes again restricted comparability, permitting analysis of fewer than half of 160 occupations

Max L. Carey and Kevin Kasunic

How reliable were the 1980 occupational employment projections? The Bureau of Labor Statistics' estimates were on target for professional and service occupations, the two fastest growing occupational groups between 1970 and 1980.[1] The projections were fairly accurate for farm, craft, clerical, and sales occupations. For the remaining three major occupational groups, BLS projections missed the mark by significant margins. BLS underestimated employment growth for managerial and administrative occupations and for nonfarm laborers, while overestimating employment in operative occupations.

Among individual occupations, the projections proved accurate for optometrists, physicians, veterinarians, elementary schoolteachers, police, and welders. Opportunities for lawyers and psychologists grew faster than anticipated. In a seeming anomaly of the impending "cashless society," cashiers and bank tellers could count on many more jobs than BLS projected, while the number of credit managers was less than anticipated.

As expected, projections for specific occupations were less accurate than for the major occupational groups. Despite some refinements, the 1980 projections were not quite as accurate as the 1975 estimates, which also spanned 10 years.[2]

In evaluating the 1980 projections, comparability again proved to be a major problem. Fewer than half of the detailed occupations studied in the base year could be evaluated, specifically, only 64 of 160 occupations.

Results by occupational group

Among the nine major occupational groups, projection errors were relatively large for nonfarm laborers, managers and administrators, and operatives. The number of nonfarm laborers employed in 1980 was underprojected by 17 percent, and the number of managers and administrators, by 13 percent. (See table 1.) By contrast, operative employment was overprojected by 11.8 percent. The average of the absolute percentage errors for all groups was 6.7 percent.

The direction of employment change was not correctly anticipated for nonfarm laborers and operatives. The number of nonfarm laborers was projected to be 3.7 million in 1980, or about 1 percent lower than the 1970 level. Instead of declining, employment in this group increased to almost 4.5 million. This projection was probably influenced by the trend of the 1960's, when employment remained at about the same level. Conversely, operative employment was projected to rise from 13.9 million in 1970 to 15.4 million in 1980, but declined to 13.8 million. The 1.6-million overestimate of operatives was the largest error in number for a major occupational group. Operative employment is concentrated in manufacturing industries, which are sensitive to economic fluctuations. After recovering from the re-

---

cession of the mid-1970's, operative employment had grown steadily and might have reached the projected level if the economy had continued to improve. Employment was at 14.5 million in 1979. The direction of employment change was correctly anticipated for managers and administrators, but employment grew twice as rapidly as projected, resulting in a 1.4-million underestimate of the 10.9 million employed in 1980. The projection of managers was probably influenced by the employment trend in 1962–67, when employment only grew from 7.4 million to 7.5 million, with very little fluctuation during that period.

Projection errors in the remaining groups were comparatively small. Differences between projected and actual employment levels ranged from less than 1 percent for professional and technical workers and service workers to 6.7 percent for salesworkers. Moreover, the projected and actual amounts of change were very close in some occupations. The estimated increase in professional and technical workers was only 2.5 percent lower than the approximately 4.5-million increase that occurred, and the estimated growth in service workers was only 3.1 percent greater than the actual increase of 3.2 million. The projections correctly identified the professional and technical workers, service workers, and clerical workers as the three fastest growing groups.

Results by specific occupation

Differences between projected and actual employment in the 64 detailed occupations ranged from an underestimate of 47 percent for psychologists to an overestimate of 89 percent for locomotive engineers' helpers. (See table 2.) The absolute percentage errors for all 64 occupations averaged 22.4 percent. About one-half of the occupations had errors lower than the average. Absolute errors ranged from a 444,000-underestimate of cashier employment in the target year to a 181,000-overestimate of telephone operators.

Employment was overprojected in slightly more than one-half of the occupations; on average, by 25.8 percent. Among the occupations in which employment was overstated by more than 50 percent were photoengravers and lithographers, patternmakers, airplane mechanics, telephone operators, and credit managers. Employment was underprojected in almost one-half of the occupations. The average underestimate was 19.5 percent. Employment in several occupations was underprojected by more than 30 percent, including cooks, bartenders, bank tellers, lawyers, and roofers.

The occupational estimates are products of the projections of industry employment and of industry-occupational staffing patterns. Many of the largest errors resulted primarily from misestimates of industry-occupational staffing patterns. The decline in the ratio of telephone operators to total employment in the telephone industry, for example, was greater than anticipated, and consequently the demand for workers in this occupation was overprojected. Staffing pattern estimates also led to large errors in the projections for locomotive engineers' helpers, psychologists, credit managers, lawyers, and roofers. Misestimates of industry employment totals, rather than industry staffing patterns, were the primary causes of large errors for some occupations. The banking industry, for example, grew much more rapidly than expected, resulting in an underprojection of the demand for bank tellers. Projection errors for cooks, bartenders, and aircraft mechanics also were largely a result of poor projections for the industries in which these workers were concentrated.

Size makes a difference

Projection accuracy was related to size of employment. When weighted by employment in each occupation, the average absolute error drops from 22.4 percent to 14.1 percent, indicating that the largest occupations generally had the more accurate projections. Relatively accurate projections for the following three categories, each with more than 1 million workers in 1980, contributed substantially to the improved results: blue-collar supervisors; elementary schoolteachers; and stenogra-

Table 1. Comparison of projected employment and actual employment in major occupational groups, 1970–80

[Workers in thousands]

Occupational group	1970	1980		Percent change		Difference between projected and actual	
		Projected	Actual	Projected	Actual	Level	Percent
Total	78,627	95,085	97,270	20.9	23.7	−2,185	−2.2
Professional and technical workers	11,140	15,500	15,613	39.1	40.2	−113	−0.7
Managers and administrators	8,289	9,500	10,919	14.6	31.7	−1,419	−13.0
Salesworkers	4,854	5,760	6,172	18.7	27.2	−412	−6.7
Clerical workers	13,715	17,285	18,105	26.0	32.0	−820	−4.5
Craft and kindred workers	10,158	12,240	12,529	20.5	23.3	−289	−2.3
Operatives	13,909	15,440	13,814	11.0	−0.7	1,626	11.8
Nonfarm laborers	3,724	3,700	4,456	−0.6	19.7	−756	−17.0
Service workers	9,712	13,060	12,958	34.5	33.4	102	0.8
Farmworkers	3,126	2,600	2,704	−16.8	−13.5	−104	−3.8

NOTE: Individual items may not add to totals because of rounding. Percent differences are based on unrounded numbers.

phers, typists, and secretaries. Sampling errors for Current Population Survey estimates diminish relatively as employment size increases, so the long-run data for large occupations would be expected to provide more reliable trends to use in the projections:

Number of workers	*Number of occupations*	*Average absolute percent error*
Total	64	22.4
Less than 50,000	18	29.5
50,000 to 99,999	9	24.9
100,000 to 299,999	14	26.3
300,000 to 599,999	11	17.2
600,000 and more	12	10.1

The direction of employment change between 1970 and 1980 was correctly anticipated for 50 of the 64 detailed occupations. Again, results were better in the larger fields of employment. Less than one-sixth of the occupations with more than 50,000 workers in 1970 had projections that were in the wrong direction, compared with more than one-third of the smaller fields. Some of the differences, however, between projected increases and actual declines, or vice versa, were relatively small.

For each occupation in which the direction of employment change was correctly anticipated, the percentage of the actual change accounted for by the projection was computed. In about two-thirds of the occupations the projections underestimated the employment change. In the remaining occupations, the projections overestimated the change.

Employment grew in 46 of the occupations between 1970 and 1980 and declined in the remaining 18. Increases were estimated more accurately than decreases. Projections of growth averaged an absolute 16.1 percent off actual employment, while those of loss averaged 38.4 percent off. Employment in two-thirds of growing occupations was underestimated. All employment declines either were underestimated or not foreseen at all.

The direction of employment change was correctly anticipated for all but two of the growing occupations. The number of elementary schoolteachers increased by about 4 percent, instead of declining by 0.9 percent. Jewelers and watchmakers increased more than 37 percent, against a projected 0.9-percent decline.

Occupations with the most rapid growth had the largest projection errors. Projected 1980 levels for those with employment increases of more than 50 percent between 1970 and 1980 averaged 30.1 percent off actual 1980 levels. Projection errors averaged only 9.4 percent for occupations with slower growth. Target-year employment usually was underestimated in the fastest-growing occupations and overestimated in those with the slowest growth. Projections were lower than actual levels in the 15 fastest-growing occupations and higher than actual in 12 of the 15 with the slowest increases.

Decreases were not anticipated in 12 of the 18 occupations that declined in employment. The projections correctly identified weaver, knitter, compositor and typesetter, locomotive engineer's helper, railroad conductor, and brake and switch operator as occupations which would decline in employment, although the rate of decrease was generally underestimated.

Testing for accuracy

One way to judge the accuracy of an occupational employment projection is to determine whether the projection or the base-year employment is closer to the target-year employment. In 45 of the 64 occupations, the projections were closer to the target than base-year employment. In the remaining 19 occupations, the projections either were in the wrong direction or overstated the employment growth by wide margins. Another way to judge projections is to compare them with the results obtained from simple alternative methods. Extrapolations of employment data by simple linear regression would have been an inexpensive and easy way of projecting. Extrapolations based on this simple method were more accurate than the projections for 46 of the 64 occupations.[3] Several of the extrapolations, however, missed targets by wide margins, which resulted in a slightly lower weighted error for the projections. The weighted absolute average error was 15.1 percent for the extrapolations, compared to 14.1 percent for the projections. Unweighted errors were about the same for both methods.

The evaluation has focused on differences between projected and actual employment *levels*, rather than differences between actual and projected employment *changes*. Generally, occupations with accurately projected levels also were accurate in terms of the proportion of actual change that was estimated. Comparisons of levels, however, have a conservative bias in that projections for occupations which have relatively little employment change tend to get better marks than those which have the most change, as demonstrated in the following occupations. Employment of psychologists was projected to increase from 33,200 in 1970 to 56,000 in 1980, but actually rose to 106,000, which means that target-year employment was underestimated by 47.2 percent. In contrast, the number of cabinetmakers was projected to increase from 70,000 to 72,700, but rose to 85,000, resulting in an underestimate of 14.5 percent. In terms of the difference between projected and actual employment levels, the projection for cabinetmakers is by far the better of the two. The projection for psychologists, however, accounted for about 31 percent of the employment increase that occurred, while the one for cabinetmakers accounted for only 18 percent. Therefore, if the measure of accuracy is the proportion of actual change that was estimated, the projection for psychologists is better. Both kinds of accuracy are important. The accuracy of level is particularly important, however, because projected levels are used in calculating replacement needs resulting from retirements and deaths.

Rating the handbook ratings

In addition to publication in *Tomorrow's Manpower Needs*, many of the 1980 projections were used as a basis for qualitative descriptions in another BLS publication, the 1972–73 edition of the *Occupational Outlook Handbook*, designed to help young people make career plans. In most cases, the handbook description of employment outlook for an occupation includes a sentence about the expected change in employment through the 1970's. The adjectives used to describe expected changes in employment requirements generally corresponded to these ranges of percent change (increase or decrease): very rapid, 40 or more; rapid, 30 to 39.9; moderate, 15 to 29.9; slow, 5 to 14.9; little or no change, 0 to 4.9. The handbook contained occupational statements for 45 of the 64 occupations for which projections were evaluated, and the standard adjectives were used in describing the outlook in 34 of these statements. Statements on only two occupations, elementary schoolteachers and telephone operators, were incorrect about the direction of employment change. The handbook expected employment in this teaching field to decline slowly, but it showed little or no change. The number of telephone operators was expected to grow slowly instead of declining moderately. The outlook description for telephone operators was misleading, but the one for elementary teachers was not.

The adjectives were on target or only one category off target for about two-thirds of the remaining statements. Rapid growth in surveyor employment was projected, for example, instead of very rapid growth. Adjectives for about one-fourth of the statements were off by two categories, but in some cases it is difficult to determine whether this degree of inaccuracy was misleading. The difference betwen moderate growth and very rapid growth, for example, does not seem as significant as the difference between moderate growth and little or no change. Adjectives for the following occupations were three categories off the mark: jewelers and watchmakers, boilermakers, and cement and concrete finishers. The outlook descriptions for these occupations likely were misleading.

The framework

The 1980 projections of occupational requirements were developed within the framework of a 1970–80 matrix that described the relationship of employment in 160 occupations and 116 industries.

The long-term data used in developing the 1970 matrix and projected 1980 matrix were obtained from a variety of sources. The primary sources of data on occupational staffing patterns by industry were the 1950 and 1960 censuses. The primary source of total employment in each industry was the Bureau of Labor Statistics' Current Employment Survey (a payroll survey) for 1947 through 1969. The Current Population Survey (a household survey) was the chief source of total employment of occupational groups and most occupations after 1960. Data for some occupations, however, were obtained from independent sources, such as professional societies and regulatory agencies.

The primary data source for occupational employment by industry was the 1960 census, because information from the 1970 census was not available. However, the 1980 data used in the analysis were largely derived from the 1980 Current Population Survey (CPS), which used the 1970 census occupational classification system. Because the Census Bureau revised its 1960 system for classifying employment by occupation for use in the 1970 census, a large proportion of the 160 occupations examined in 1970 were not sufficiently comparable for evaluation.[4]

According to the Census Bureau, all nine occupational groups had 96 percent or better comparability between the two classification systems. Specifically, if the 1960 labor force data were retabulated, 95 percent or more of the employment reported in a particular major occupational group under the 1960 classification system would remain in the same group under the 1970 system, and these workers would represent 95 percent or more of the total for that group. For detailed occupations, there was far less comparability. Of the 297 occupations in the 1960 census classification system, only 171 had 90 percent or better comparability in the 1970 system. About one-half of these occupations, however, were not included in the matrix. In addition, the accuracy of some of the projections that were based on historical data from sources other than the census could not be verified. After eliminating occupations which were less than 90 percent comparable and those which had verification problems, the evaluation of projections was limited to 64 of the 160 detailed occupations covered in the matrix.

In addition to the comparability and verification problems, the comparison of actual and projected data were hampered by the sampling errors of the CPS. For a CPS estimate of 50,000, for example, the standard error would be about 6,700 or roughly 13 percent of the employment level. This much variance would have a great impact on evaluating accuracy, for projections averaged only 28 percent off the CPS-derived 1980 estimates for occupations with employment of less than 100,000.[5]

Data constraints precluded construction of a 1980 matrix with actual data comparable to the projected 1980 matrix. Consequently, 1980 employment levels for most occupations were estimated from CPS data, the primary source of occupational data for matrices between decennial censuses. Data on 1980 employment were also obtained from independent sources, such as professional associations, in cases where the 1960 and 1970 matrices used these sources rather than the census or CPS.[6]

Table 2. Comparison of projected, simulated, and actual 1980 employment in selected occupations

[Workers in thousands]

Occupation	1970	1980			Difference between projected and actual		Difference between simulated and actual		Percent change		
		Projected	Simulated	Actual	Level	Percent	Level	Percent	Projected	Simulated	Actual

Methods and assumptions. The basic approach used to estimate future occupational employment requirements was to project total employment by industry, project occupational staffing patterns (ratios) by industry, and then multiply the industry totals by the ratios to obtain occupational estimates. The results were then summed across industries to obtain occupational totals.

Projections of the occupational structure of each industry were based on examination of historical statistics and the analysis of the factors that influence occupational structure changes, such as new technology and changes in the product mix of industry. Employment requirements for many occupations, however, were projected independent of their relationships to industry employment. The projection of schoolteachers, for example, was based on an analysis of trends in pupil-teacher ratios and the projected school-age population. This technique was preferred in cases where such reliable predictive relationships could be established.[7]

The 1980 occupational projections embodied certain assumptions about the size of the labor force, Armed Forces strength, the rate of unemployment, and other selected assumptions. Full employment was assumed in the target year and defined as a civilian labor force with a 3-percent unemployment rate. A total labor force of 100.7 million was projected for 1980, and it was assumed that 2.7 million persons would be in the Armed Forces, yielding a civilian labor force of 98 million. With the assumed unemployment rate, the result was projections of 95.1 million employed and 2.9 million unemployed workers. The employment number was used as a control total for the occupational projections.

Total employment underestimated

The projection of total employment for 1980 was 2.2 percent below the actual 97.3 million. Ironically, the error would have been greater if either the labor force or the unemployment rate had been accurately projected. The labor force projection was 5.7 percent lower than the actual 106.8 million, primarily because the number of women entering the labor force was greater than anticipated.[8] In addition, Armed Forces strength was overprojected by 600,000. The net result was a 6.7-million, or 6.4-percent, understatement of the civilian labor force (workers in thousands):

Labor force group	*Projected*	*Actual*	*Percent difference*
Total	100,700	106,821	-5.7
Armed Forces	2,700	2,102	28.4
Civilian labor force	98,000	104,719	-6.4
Employment	95,085	97,270	-2.2
Unemployment . . .	2,915	7,448	-60.9

The unemployment rate in 1980 averaged 7.1 percent, instead of the assumed 3 percent. Consequently, the number of unemployed workers was underestimated by about 4.5 million. In terms of employment, however, this error offset a large part of the error in the civilian labor force projection. If the civilian labor force had been projected correctly, the unemployment assumption would have resulted in a 4.4-percent overstatement of 1980 employment, rather than the 2.2-percent underestimate that occurred. Conversely, if the unemployment rate had been accurately anticipated, the civilian labor force projection would have resulted in a 6.4-percent understatement of employment.

The recovery and expansion that followed the 1974–75 downturn came to an end in 1980, as the economy felt the effects of the 1979 oil-price shock. After declining from 8.5 percent in 1975 to 5.8 percent in 1979, the unemployment rate rose to 7.1 percent in 1980. Even if the economy had continued to improve, however, it is not likely that unemployment would have declined to the 3-percent rate assumed in the projections. The economic downturn of 1980 affected employment in some occupations more than others. Because unemployment rates for individual occupations were not specified in the assumptions, however, the effect of economic conditions on the accuracy of a projection for any given occupation is difficult to measure.

Simulated projections

A simulated matrix based on projected 1980 industry employment totals and 1970 staffing patterns for each industry was developed to determine whether these base-year patterns would have resulted in better or worse occupational employment estimates than the projected patterns that were used. Neither was clearly superior, but the 1980 estimates for many occupations changed substantially.[9]

The projections were more accurate than the simulations for 6 of the 9 major occupational groups. (See table 3.) However, the average absolute error for all groups declined from 6.7 percent to 5.7 percent as a result of the simulations. The improvement in this average was largely because of a much more accurate estimate for nonfarm laborers. Employment in this group was projected to increase less than 1 percent between 1970 and 1980, but actually rose 19.7 percent. The simulated estimate was very close to actual employment. Simulations also were more accurate than projections for managers and farmworkers.

The simulation improved the projection accuracy for exactly one-half of the 64 detailed occupations in the study and reduced it for the remainder. (See table 2.) The average absolute percentage error increased slightly, from 22.4 percent to 22.9 percent. Errors from the simulation ranged from a 55-percent understatement of psychologists to a 81-percent overstatement of locomotive engineers' helpers. The same occupations had the most extreme errors in the projections, and the values

Table 3. Comparison of projections and simulations of 1980 employment by occupational group

[Workers in thousands]

Occupational group	1980			Difference between projected and actual		Difference between simulated and actual	
	Projected	Simulated	Actual	Level	Percent	Level	Percent
Total	95,085	95,085	97,270	−2,185	−2.2	−2,185	−2.2
Professional and technical workers	15,500	15,117	15,613	−113	−0.7	−496	−3.2
Managers and administrators	9,500	9,910	10,919	−1,419	−13.0	−1,009	−9.2
Salesworkers	5,760	5,541	6,172	−412	−6.7	−631	−10.2
Clerical workers	17,285	16,763	18,105	−820	−4.5	−1,342	−7.4
Craft and kindred workers	12,240	12,143	12,529	−289	−2.3	−386	−3.1
Operatives	15,440	15,830	13,814	1,626	11.8	2,016	14.6
Nonfarm laborers	3,700	4,377	4,456	−756	−17.0	−79	−1.8
Service workers	13,060	12,695	12,958	102	0.8	−263	−2.0
Farmworkers	2,600	2,709	2,704	−104	−3.9	5	0.2

NOTE: Details may not add to totals because of rounding. Percent differences are based on unrounded numbers.

were about the same. However, considerable differences appear when the occupations are ranked according to accuracy. Only two occupations were among the 10 with the most accurate projections in each version. Even among each top 20, there were only nine occupations in common. Similarly, only two occupations were among the 20 with the worst projections in each version.

The simulation increased projection errors substantially for several occupations. One of the better projections, a 5-percent underestimate of elementary schoolteachers, was raised to a 41-percent overestimate. Because these teachers declined as a percentage of total employment in the educational services industry between 1970 and 1980, the use of 1970 staffing patterns in the matrix resulted in an overstatement of employment.[10] Some other occupations with much less accurate projections as a result of the simulation were veterinarians, optometrists, compositors and typesetters, and postmasters. In contrast, projection errors were reduced significantly in several occupations, including credit managers, airplane mechanics, photoengravers and lithographers, and locomotive engineers. Many of the occupations most affected by the simulation were concentrated in relatively small numbers of industries, thus reducing chances of compensating errors in industry-occupation cells in the matrix.

Similar patterns were observed in both the projections and the simulations. The largest occupations generally had the most accurate 1980 estimates. In each case, the direction of employment change was correctly anticipated in about 5 out of every 6 occupations. Employment in about two-thirds of the growing occupations was underestimated, and nearly all employment declines were underestimated.

The simulation exercise indicated that the extrapolation of staffing patterns did not, on average, produce more accurate projections for detailed occupations than the assumption that the patterns would not change over the projection period. This suggests that future work should concentrate on analysis of factors that affect the patterns, rather than extrapolations based on limited observations.

Projections for 1975

The 1980 occupational projections were slightly less accurate than those previously developed by the Bureau for 1975. The 1980 estimates have the disadvantage of being based on more dated statistics on occupational staffing patterns of detailed industries as the 1960 census was the most recent source for both projections. However, a larger number of CPS annual estimates of total employment in each occupation was available for the 1980 projections.

Although the 1975 projections were published with a 1960 matrix base, CPS estimates of annual employment were available annually through 1965 at the time the projections were being developed and were used in the analysis. Annual CPS estimates through 1970 were available for the 1980 projections. Therefore, both the 1975 and 1980 projections covered a 10-year span.

The projection of total civilian employment in 1975 was 2.9 percent higher than the actual level of 84.8 million. The 1980 projection, by contrast, was 2.2 percent lower than the actual level of 97.3 million. The difference is explained primarily by the underlying labor force projections. In both periods, labor force participation rates for women rose more rapidly than expected, resulting in underestimates. However, the labor force was underestimated by only 2.3 percent in 1975, compared with 5.7 percent in 1980. For each year, it was assumed that Armed Forces strength would be 2.7 million and the unemployment rate would be 3 percent. The number of military personnel was overestimated by about 24 percent in 1975 and by more than 28 percent in 1980. The economic recession of the mid-1970's negated the assumption of a full-employment economy in 1975. The unemployment rate in 1975 averaged 8.5 percent, or almost triple the assumed rate. Although the downturn in 1980 was not as severe, the unemployment rate averaged 7.1 percent.

Among the comparable detailed occupations, the 1975 projections averaged 21.1 percent off the mark, while the 1980 estimates averaged 22.4 percent off. Accuracy improved, however, for about one-half of the occupations. The largest error among the 1975 projections, a 136-percent overestimate of plasterers, was reduced to 29 percent. Large projection errors for civil engineers and knitters, loopers, and toppers also were reduced. Occupations with worse projections in 1980 included airplane mechanics, lawyers, telephone operators, locomotive engineers' helpers, and crane, derrick, and hoist operators.

Only two occupations were among the 10 with the most accurate projections for each year. Among the leading 20, there were eight occupations in common. In addition, relatively few of the same occupations were among the least accurate projections for each year.

Again, similar patterns were observed in both sets of projections. The largest occupations usually had the most accurate projections. The direction of employment change was correctly anticipated for about 5 out of every 6 occupations in each set. In both the 1975 and the 1980 projections, errors for occupations that declined in employment averaged more than twice as high as those with employment growth. Nearly all employment declines were underestimated. However, employment in about one-half of the growing occupations was underprojected in 1975, compared with two-thirds in 1980.

The 1975 projections performed better against simple extrapolations than the 1980 projections, but the extrapolations for these two target years were not based on the same number of employment observations. For the 1975 study, annual employment data were available only for 6 years, whereas most of the extrapolations to 1980 were based on 9 years of data.

The earlier evaluation did not include a simulation of target-year employment using base year occupational staffing patterns and projected industry employment totals. Instead, it focused on a simulation based on projected staffing patterns and actual 1975 employment totals for each industry, which disclosed that errors in the occupational employment projections were mostly a result of the staffing patterns. Unfortunately, data limitations precluded a similar study of the 1980 projections.

New projections

Since the 1980 projections were published, the Bureau has taken steps to improve its occupational outlook program. Recently, the first matrix to be developed from data from the Occupational Employment Statistics survey was completed and projected to 1990.[11] Previous matrices were based largely on census information on trends in staffing patterns from decade to decade. Because census data are collected only once every 10 years, they do not capture the latest developments in occupational employment requirements in different industries. The occupational employment survey provides much more timely information, as it collects data on a 3-year cycle. The survey also is more specific in its definition of occupations and has a larger sample than the census-derived sample.[12]

Both this study and that of the 1975 projections indicated weaknesses in industry-occupation staffing patterns. The evaluation of the 1980 projections disclosed that mechanical extrapolation of staffing patterns in the matrix does not necessarily produce better results than static patterns. In preparing the 1990 survey-based projections, patterns were extrapolated only when detailed analysis showed that there were reasons to expect them to change. As a result, the matrix has more industry-occupation cells that remain static between the base and target years.

The 1980 projections were based on a single set of assumptions. Three alternative sets of occupational employment projections were developed for 1990 from different assumptions about growth of the labor force, production, productivity, and other factors. While many users of the data may prefer a single set of estimates, the Bureau's evaluations have demonstrated a wide range of errors in previous occupational projections. In addition, a single estimate concerning the future inevitably causes users to attribute a precision to it that should not be afforded. Alternatives also are of more value to planners who are concerned with how differences in the assumptions might affect the demand for some occupations more than others. ☐

FOOTNOTES

[1] The Bureau's occupational projections for 1980 were published in *Tomorrow's Manpower Needs*, Volume IV, revised 1971, Bulletin 1737.

[2] See Max L. Carey, "Evaluating the 1975 projections of occupational employment," *Monthly Labor Review*, June 1980, pp. 10–20.

[3] CPS annual averages of employment for 1962 through 1970 were extrapolated for the 51 occupations which use the Census and CPS as data sources for the matrix. Twelve other occupations had matrix estimates based on independent sources. Rather than attempting to reconstruct annual data from independent sources, estimates from 1960 and 1970 matrixes were extrapolated for these occupations. An extrapolation was not developed for osteopaths because an estimate for this occupation was not available from the 1960 matrix. The extrapolation for locomotive engineers' helpers resulted in negative employment in 1980; the negative number was arbitrarily adjusted to a positive level of 100 workers.

[4] *Technical Paper 26 1970 Occupation and Industry Classification System in Terms of Their 1960 Occupation and Industry Elements.* (Washington, U.S. Bureau of the Census. 1972.)

[5] The formula and parameters established from the CPS were not developed specifically for use in identifying standard errors of employment in detailed occupations, but, nevertheless, should approximate the magnitude of error.

[6] For some occupations, the 1970 matrix employment levels and 1970 CPS employment levels were identical. In these cases, the 1980 CPS employment was accepted without adjustment. For many other occupations, however, differences existed between CPS and matrix employment levels for 1970, even though the matrix estimates were not developed from independent sources. If a difference was large, the occupation was not included in the evaluation. The 1980 CPS employment levels were adjusted to account for small differences in the 1970 numbers from the CPS and the matrix. If matrix employment for an occupation in 1970 was 2 percent higher than CPS employment, for example, the 1980 CPS employment was increased by 2 percent. A similar procedure was followed in preparing employment estimates from data obtained from independent sources.

[7] For a detailed discussion of the methodology used in developing employment projections, see *Tomorrow's Manpower Needs*, pp. 3–6.

[8] The total labor force participation rate for women was projected at 43.0 percent for 1980. See "The United States economy in 1980," *Monthly Labor Review*, April 1970, pp. 3–34. The labor force participation rate for women in 1980 was actually 50.9 percent. For an evaluation of the 1980 labor force projections, see Howard N Fullerton, "How accurate were projections of the 1980 labor force?", elsewhere in this issue.

[9] Other simulations based on different combinations of actual and projected data on staffing patterns and industry employment totals would have been interesting. The occupational totals resulting from a matrix based on 1970 staffing patterns and actual 1980 industry employment levels could be compared with the actual 1980 occupational totals to determine the extent to which static patterns alone would have affected projection accuracy. Similarly, simulations could be developed by combining actual 1980 staffing patterns with projected 1980 industry employment, and projected 1980 staffing patterns with actual 1980 industry employment. These two simulations could be used to determine whether the projections of staffing patterns or the projections of industry employment contributed most to the projection error for each occupation. Unfortunately, some of the data needed for these studies were unavailable. The Current Population Survey (CPS), which was the primary source of data on total employment by detailed occupation for 1980, gives staffing patterns only for industry groups. The Bureau's establishment survey, which is the source of data on wage and salary employment in each industry, changed from the 1967 Standard Industrial Classification (SIC) to the 1972 SIC in 1978, and, consequently, projected and actual employment levels for 1980 are not comparable for many industries.

[10] Actually, the 1970 staffing patterns for elementary schoolteachers were not the sole source of the overprojection of employment in the simulated matrix. The error was compounded by an overprojection of total employment in the educational services industry for 1980. If the industry projection had been correct, the overprojection of elementary teachers would have been reduced by more than one-third.

Shortages of machinists: an evaluation of the information

Shortages of machinists appear to exist but the statistics that quantify the shortages are unreliable; some employers can cope by offering higher wages, others may use technological improvements or increase training

Neal H. Rosenthal

Is there a shortage of machinists? Will machinists be in short supply in the future? Various studies offer conflicting answers that cannot be resolved with available data. However, an examination of Current Population Survey, Area Wage Survey, and other data can shed light on *why* the conflict exists. This article undertakes such an examination.

During the past few years many articles dealing with current and expected future shortages of machinists were published in national periodicals. Their basic conclusions are generally consistent: Employers currently are not able to hire as many skilled machinists as they would like; current training is not sufficient to alleviate shortages; and similar conditions have existed for some time. Concern about the future supply is also based on the expected decline in the number of 18- to 24-year-old workers in the 1980's. However, different conclusions result from studies concerning technological change. They generally state that the need for manual labor in factories, especially highly skilled machinists, will be reduced significantly in the future.

Because of the different viewpoints of these studies, future supply-demand conditions for machinists are unclear. Furthermore, very little of the statistical information used to present both sides is based on "hard data." Most data are obtained from employers in surveys that have questionable reliability. Existing Federal programs do not collect data on shortages of workers in specific occupations; such data would be very expensive to collect and because of their complexity their reliability would be questionable. Also, information about future occupational shortages is very limited. Nevertheless, by summarizing and analyzing a wide variety of data, insights can be gained into the problems and issues.

Definition of terms

Shortages. Data are often misused or misinterpreted because definitions of terms are not clearly specified. Shortage, as used here, means that sufficient workers are not available and willing to work at the existing wage level. Traditional economic theory, which states that if wages are raised, supply will increase because more workers will seek jobs, is consistent with this definition. However, it usually takes time to acquire the required skills, so demand may not be met in the short run. Under these conditions, wages can be expected to rise as employers hire trained workers from each other, overtime will be used to meet production schedules, and less skilled workers will be employed. These factors are apt to raise prices and reduce productivity.

In addition, it is likely that employers would raise wages for trainees in an attempt to attract qualified

---

Neal H. Rosenthal is chief of the Division of Occupational Outlook, Bureau of Labor Statistics.

workers to machinist training programs and thereby reduce future shortages. However, wages alone do not affect one's career choice; working conditions, social status, and personal abilities and preferences are also considerations.

Hence, the job market for an occupation is very complex. Workers employed in a specific occupation may shift to another occupation; die; retire; change jobs by switching employers but remaining in the same occupation; or lose their jobs and become unemployed. Most occupations also have several skill levels, and employees can change jobs within the same occupation by moving up the skill ladder. At the same time that individuals leave an occupation or change jobs within it, others enter the occupation. They come from outside the labor force, as do new young workers and persons who are returning to work after raising a family, pursuing some additional education, or a short period of retirement. Entrants also may come from another occupation or from the ranks of the unemployed. Unfortunately, available data do not quantify these various situations accurately.

Machining occupational classification. Many discussions about shortages of machinists are confusing because it is unclear which jobs are included in the job classification. For example, the occupational titles of machinist, machining occupations, and metalworking occupations are often used to mean different groups of workers but sometimes they are used interchangeably. Furthermore, because consistency in occupational definitions does not exist among all Federal statistical programs, data on machinists from various sources may reflect different groupings of workers. For example, the occupational classification used by the Bureau to collect data on wages of machinists from the Area Wage Survey Program is not identical to the classification in the Current Population Survey (CPS). Similarly, the definition of machinists for which data are compiled on job openings registered by employers with the U.S. Employment Service does not match the CPS definition. Data on vocational programs also are classified differently.[1] The coverage of machinists in the various surveys conducted by employer associations to identify shortages also differs from that used in most Federal statistical programs. Inclusion of specific jobs within the broad term machinists also changes from one employer survey to another and probably among employers responding to the same survey. Therefore, results from one survey should not be compared with data based on other surveys unless consistency of job content has been ensured. Unfortunately, such comparisons have been made in the past even though the data were not comparable. This practice has contributed to much of the perplexity concerning shortages of machinists.

To avoid confusion in this article, the CPS definition of machinists was used because that survey provides more data than any other single source about employment and unemployment trends for workers in machining occupations. Furthermore, many other statistical series are reasonably compatible with the CPS or can be related through crosswalks.

Machining workers are classified in two skill-level groups in the CPS—skilled workers and operatives. Three skilled machining occupations identified separately in the CPS are discussed here—machinists, tool-and-die makers, and job and die setters. Data for five operative occupations—drill-press operatives; grinding-machine operatives; lathe and milling-machine operatives; punch-press-machine operatives; and other precision machine operatives—are also analyzed.

Each of these occupations includes workers found in a variety of jobs as classified by employers. For example, the occupation of tool-and-die maker in the CPS's conducted during 1972–80, includes 35 separate job titles, including diemaker, diesinker, jig-bore-tool maker, tool adjuster, and jig-and-fixture builder. Similarly, skilled machinists comprise about 25 specific job titles such as fitter-machine, precision machinist, toolroom machinist, lathe machinist, and aircraft machinist. Lathe and milling-machine operatives include more than 60 different job titles, such as lathe operator, lathe turner, tool-lathe operator, milling-machine operator, and gear cutter.

It should be pointed out that CPS statistics are compiled as if there were a clear break in skills between occupations rather than a continuum within each category. For example, all workers in the machinist or the lathe operators category do not perform at the same skill level. Also, the skills of workers who are counted in the skilled machining occupations in the CPS overlap with those of some operatives.

Machinists in the 1970's

Employment. Combined employment in the three skilled machining occupations covered separately in the CPS—job and die setters, metal; machinists; and tool-and-die makers—increased from 655,000 to 834,000, or 27 percent, between 1972 and 1980.[2] Job growth averaged 22,400 a year. (See table 1.) In comparison, employment in manufacturing industries, where most machinists are employed, grew by only 6 percent over the same period. Machinist employment grew from 377,000 to 567,000, or 50 percent, but the other skilled machining occupations—job and die setters and tool-and-die makers—declined slightly. During the 1975 recession, employment did not decrease significantly for any of the skilled machining occupations.

Employment in each of the operative machining occupations fell between 1972 and 1980 or remained at

Table 1. Employment in machining occupations, annual averages, 1972–80

[Numbers in thousands]

Occupation	1972	1973	1974	1975	1976	1977	1978	1979	1980
Skilled machining occupations, total	655	682	735	731	758	768	773	824	834
Job and die setters, metal	94	93	97	96	92	97	98	90	91
Machinists	377	402	461	461	478	478	493	552	567
Tool-and-die makers	184	187	177	174	188	193	182	182	176
Operative machining occupations, total	625	595	601	489	508	524	542	562	502
Drill press	75	77	69	61	65	62	64	67	61
Grinding machine	130	140	152	132	133	126	129	143	134
Lathe milling machine	123	136	137	118	106	121	125	123	114
Punch stamping press	157	175	170	130	155	152	156	158	127
Other precision machines	140	67	73	48	49	63	68	71	66

roughly the same level. For operative machining occupations as a group, employment dropped by an average of 15,400 annually. However, during the 1975 recession, employment decreased significantly in each of these occupations.

Unemployment. Unemployment rates for machinists and tool-and-die makers were lower than those for craftworkers as a whole in each year from 1972 to 1980. (See table 2.) The unemployment rates for tool-and-die makers were very low—less than 3 percent—for most of the period. However, even for this occupation the rate jumped significantly to 7.1 percent during the 1975 recession, although it declined to 3.3 percent in 1976. The unemployment rate for machinists was lower than that for tool-and-die makers prior to the 1975 recession, but was higher after 1975. The unemployment rate for job and die setters was also relatively low in the 1970's. During the 1970's, the unemployment rate for the skilled machining occupations was lower than that for durable goods manufacturing as a whole, in which more than 80 percent of all skilled machining workers are employed. Unemployment rates for operative machining occupations were generally higher than average.

Earnings. Earnings data for machinists, tool-and-die makers, and machine-tool operators are collected through the Bureau's Area Wage Surveys. The definitions for both machinists and tool-and-die makers used in these surveys are not identical to those in the CPS, but they are very comparable. However, the skill level of the machine-tool operators for which wage data are collected is much higher than that which the average worker reported in operative machining occupations in the CPS.

The hourly earnings of machinists, tool-and-die makers, and machine-tool operators from the Area Wage Surveys varied only slightly within the same city for each year in which data were available during 1972–80. In general, tool-and-die makers earned a little more than machinists who in turn earned slightly more than machine-tool operators, although the pattern varied among cities. (See table 3.) For each occupation, there were some significant earnings differentials among cities.

Workers in the machining occupations covered in the BLS Area Wage Surveys had higher average hourly earnings than all production workers in manufacturing industries in the same city as reported in the Bureau's Current Employment Statistics program. Between 1972 and 1980, the wages of workers in the machining occupations relative to all production workers remained the same or declined slightly in five cities for which data are readily available.

Training. Data on registered apprenticeships indicate that completions declined significantly between 1970 and 1980 for machinists and tool-and-die makers. The number of machinist apprenticeship completions fell from 3,822 to 1,905 between 1970 and 1975, increased to nearly 3,000 in 1977, and then decreased to 2,450 in 1979. Tool-and-die makers followed a similar pattern but their decline from 1970 was even greater. The following tabulation shows the number of completions and additions to registered apprenticeship programs in 1972–79 for machinists and tool-and-die makers:

	Machinists		*Tool-and-die makers*	
	Completions	*Additions*	*Completions*	*Additions*
1972 . .	3,695	—	3,825	—
1973 . .	2,357	—	2,716	—
1974 . .	2,047	6,526	2,051	4,934
1975 . .	1,905	4,858	1,849	2,900
1976 . .	2,526	5,567	1,901	3,888
1977 . .	2,967	5,488	2,387	5,150
1978 . .	2,859	6,385	2,311	5,501
1979 . .	2,450	6,397	1,807	5,379

However, workers who complete apprenticeship programs are not new entrants to an occupation in an accounting sense, because apprentices are counted in the employment totals for the occupation. Adding them as new workers, when they complete training, would result in double counting. Data on the additions to apprenticeship programs each year provide a better measure of new entrants to an occupation. These data show that the number of new additions to apprenticeship programs averaged between 5,000 and 6,500 for machinists and 3,000 to 5,500 for tool-and-die makers from the mid- to late 1970's. They do not display the declining pattern shown by completions.

Training programs for tool-and-die makers, machine-tool operators, and machine-shop occupations also are offered in public vocational educational programs. Data on completions are very sparse and their meaning is vague because both secondary and post-secondary completions are added together in reports. Thus, the completions may reflect a 1- or 2-year program or just one course. Furthermore, the skills of the individuals completing these programs are minimal compared to those of persons finishing apprenticeship programs, and completion of vocational courses does not qualify individuals for journeyman positions. Generally, those completing these programs subsequently enter apprenticeship programs in order to pursue careers in machining occupations. In 1978, 2,400 students completed tool-and-die making training in public vocational schools, 3,400 completed training in machine-tool operation, and 32,000 completed training in other machine-shop occupations.

Implications of the data

The data presented above do not prove or disprove that shortages of machinists exist. Nevertheless, they are compatible with the existence of such shortages. The data indicate that skilled machinists are important in production activities: During the 1970's, they increased as a proportion of total employment, and even during the 1975 recession, their employment did not decrease. The very low unemployment rates for skilled machining workers during the 1970's also is very compatible with a shortage of workers. However, it is doubtful that general shortages of machine operatives occurred during this period because of their relatively high unemployment rates. However, during some years, these rates were very low for certain operative occupations and indicate possible shortages.

Unlike the data on unemployment, those on earnings of machining workers do not show a pattern that would, in theory, be expected with the existence of shortages. When there are shortages in an occupation over time, its wages should increase relative to those of other workers who are not in limited supply. This was not the case for machinists, as the differential wage between machinists and all production workers did not change significantly. However, the constant wage differential is not definitive proof that a shortage did not exist. Wage structures are interconnected in complex ways, and there could be conditions that would not allow the differential to change significantly despite a shortage. For example, the industries employing many machinists and tool-and-die makers have numerous small firms that compete for work through bids in response to service requests. If one firm raises its wages, it must also raise its bids, and risk losing work. Thus, raising wages to attract workers may be counter-productive, if the new workers are subsequently not needed because work is not available.

Table 2. Unemployment rates for machining occupations, annual averages, 1972–80

[In percent]

Occupation	1972	1973	1974	1975	1976	1977	1978	1979	1980
Total, all workers	5.6	4.9	5.6	8.5	7.7	7.0	6.0	5.8	7.1
Craftworkers	4.3	3.7	4.4	8.3	6.9	5.6	4.6	4.5	6.6
Job and die setters, metal	3.1	1.2	2.2	7.8	4.0	3.2	2.8	3.5	4.8
Machinists	3.2	1.9	2.2	7.0	5.9	3.8	3.1	2.7	4.8
Tool-and-die makers	4.0	1.6	2.5	7.1	3.3	2.0	2.6	.9	2.8
Nontransport operatives	7.6	6.1	13.2	14.7	10.8	9.5	8.1	8.4	12.2
Drill press	9.5	6.3	9.9	20.0	15.8	9.5	4.9	5.8	13.4
Grinding machine	5.6	2.2	4.5	11.8	7.1	4.7	4.9	3.1	8.8
Lathe milling machine	5.1	1.8	3.4	13.1	8.8	5.3	4.6	2.9	9.1
Punch stamping press	8.2	4.7	9.5	23.2	12.1	9.4	8.0	12.9	24.1
Other precision machines	5.8	3.4	4.9	14.5	10.3	5.6	7.0	6.7	12.8
Total, durable goods manufacturing	5.4	7.9	5.4	11.3	7.7	6.2	4.9	5.9	8.9

Table 3. Earnings of workers in selected machining occupations relative to those of all production workers, selected cities, 1972 and 1980

City and occupation	1972	1980
Boston:		
Machinists	1.47	1.22
Machine-tool operators	1.43	1.12
Chicago:		
Machinists	1.31	1.32
Tool-and-die makers	1.41	1.30
Machine-tool operators	1.26	1.30
Houston:		
Machinists	1.29	1.23
Tool-and-die makers	1.17	1.15
Baltimore:		
Tool-and-die makers	1.32	1.31
Machine-tool operators	1.15	1.14
Cincinnati:		
Tool-and-die makers	1.30	1.28
Machine-tool operators	1.24	1.17

Trends in training through apprenticeship programs shed some light on the job market situation for machining workers because apprenticeship training is provided by employers. During periods of shortages or expected shortages, employers should be willing to increase training. However, during the 1970's, apprenticeships decreased, implying that shortages did not exist or that they were not severe enough to warrant increased training opportunities. However, the employer surveys conducted by associations discussed earlier in this article not only indicate the existence of shortages, but expanded apprenticeship training programs. But many employers prefer not to have registered apprenticeship programs because these must strictly conform to Department of Labor regulations, and last for 4 years. Many employers evidently feel they can train workers to acceptable standards in less time through nonregistered programs. Reducing the length of training is very consistent with the existence of shortages. Data on enrollment and completions of nonregistered programs do not show up in Federal statistics.

As indicated previously, specific data designed to measure occupational shortages are not compiled by the Federal Government. Although data are available on job orders placed with U.S. Employment Service offices throughout the country, they are not comprehensive, covering only an estimated 10 to 15 percent of all job openings, and they are not statistically valid for analyzing year-to-year changes.

However, a 1980 pilot survey of job vacancies in Massachusetts, conducted to test the collectibility of such data, point to the existence of a shortage of machinists—at least in that State. The job vacancy rate (vacant jobs divided by total employment) for machinists was 13.3 percent in 1979 and 12.5 percent in 1980,[3] significantly higher than for any other occupation in the State. High vacancy rates (over 4 percent in each year) also were found for mechanical engineers, computer scientists, registered nurses, licensed practical nurses, and computer programmers. These occupations are traditionally placed in the "shortage" category, and it is significant that the vacancy rate for machinists was much higher.

Journal articles analyzing employment and shortages of machinists often discuss the age distribution of these workers. Much is written that the average age of machinists is increasing. Such reports generally imply that the age distribution of machinists is becoming skewed toward the older age groups; but data on the age distribution of machinists and job and die setters collected in the CPS dispute this conclusion. For example, between 1972 and 1980, the proportion of these workers who were 55 to 64 years old declined, and significant increases were recorded in the 20 to 24 and 25 to 34 age groups. The rise in the younger group followed the trend of the total population and of craftworkers as a whole. Some of the employer surveys we have mentioned, which indicate shortages and the need for more training, also imply that the increasing average age of these workers is not a problem.

A look at the 1980's

Because machining workers are key to many types of industrial production, economic and industrial planners are very concerned about the future job market for these workers. The issue is particularly significant to those concerned with the capability of U.S. industry to cope with a major defense buildup. Some insights about this topic can be gained from BLS projections of employment in machining occupations.[4]

Until 1980, the Bureau's occupational projections were developed using historical employment data derived from the CPS. However, in 1980, the Bureau shifted the base for current occupational employment from the CPS to employment data generated by the Occupational Employment Statistics (OES) Survey. OES data are obtained by mail questionnaire from a sample of establishments that is designed to produce estimates of industry staffing patterns. Specific occupational definitions are listed on the questionnaire for each major occupation in an industry, and up to 16 different machining occupations can be found on an industry questionnaire. For these reasons, as well as others related to survey methods and procedures, OES survey-based employment data are believed to be more accurate than those derived from the CPS for measuring employment data by detailed industry. However, because national OES survey data were not available prior to 1978, analysis of historical data is CPS-based.

Employment data on machining occupations in the CPS and the OES survey are not strictly comparable because of differences in definitions, as well as in survey procedures and methods. For example, the 1980 CPS total for skilled machining occupations—job and die setters, machinists, and tool-and-die makers—was 834,000, about 266,000 higher than the 568,000 in 12 separate OES occupations that are in theory comparable to the three CPS groups combined. Actually, the numbers of job and die setters were reasonably close, 91,000 (CPS) and 93,300 (OES), as were the totals for tool-and-die makers, 176,000 (CPS) and 170,000 (OES). However, figures for machinists varied considerably, 304,000 (OES) and 567,000 (CPS).

Data in the CPS are collected directly from individuals who respond to questions about their work activities. It is very likely that operators of numerically controlled machine tools, and the highly skilled "machine tool operators, combo" who operate several machines are included in the CPS machinist category rather than in the operative category, "other precision machine operatives." These workers probably consider themselves to be machinists rather than machine operators, and they are apt to report to a CPS interviewer in a manner that would result in their being classified as the former. Their salaries also are very close to, if not higher than, machinists' and tool-and-die makers', and far exceed those of other workers in the machine operator class. If one assumes that these workers are counted in the CPS machinist category, and adds their OES employment (52,700 numerically controlled machine tool operators and 170,700 machine tool operators, combo) to the OES employment of skilled machining workers, the OES total would be 791,300, compared with 773,000 in the CPS.

The above discussion was designed to establish reasonable comparability of data on employment of skilled machining workers based on CPS and OES survey data. If the data are reasonably comparable, comparisons can be made between historical and projected data. As noted earlier, employment in skilled machining occupations grew an average of 22,400 a year between 1972 and 1980. In the Bureau's three alternative projections of employment to 1990, the average annual growth of employment for skilled machining workers (including numerically controlled machine tool operators and machine tool operators, combo) ranged from 11,900 to 23,200 from 1980 to 1990. In each projection, the rate of growth of employment is expected to be slower than in the 1970's, and only in the high-trend model is the 1980-to-1990 numerical average annual growth similar to that of the 1970's. (See table 4.)

Conclusions

Information about the job market for skilled machining workers during the 1970's is consistent with the existence of shortages. However, statistics generated by ongoing government data collection programs do not provide the information necessary to quantify the shortage. Quantitative data from surveys conducted by employer associations are statistically unreliable and probably overstate the numerical shortage. Some employers do not experience a shortage of skilled machining workers because they offer higher than average wages, benefits, or both. Also, the severity of the shortages varies among geographic areas.

Employers can deal with shortages in many ways. Some can offer wages that are higher than other employers in their locality and therefore are able to hire the workers they need, while others implement technological gains or increase training.

Those using technological development to cope with shortages may expand their use of numerically controlled machine tools, machining centers, adaptive control, digital readout, manual data input control, improved cutting-tool materials, and group technology.[5] However, because technological improvements often require substantial capital investment, smaller employers may have great difficulty in obtaining the required funds and therefore cannot make the desired innovations.

Many employers have increased training in an effort to reduce shortages of skilled machining workers. Skilled machining workers must be trained on the job; therefore, unless employers cooperate, additional workers will not become available. However, training is expensive and many employers are not able to significantly expand their training efforts.

General shortages of skilled machinists should not worsen during the 1980's, but they may be marked in some localities. For example, if defense purchases were to rise rapidly during a short time frame and affect industries in a specific area, the shortage could become so acute that the planned increases in production could not occur.

In general, however, unless programs are designed to foster action on the part of employers, current shortages are not likely to be reduced significantly. Some specific program may be necessary to provide employers with an incentive to expand the rate at which new technology is introduced or to increase the number of workers trained each year.

Because skilled machining workers must be trained on the job in 3- to 4-year programs, increases in such programs providing machining skills offered in vocational education and Comprehensive Employment and Training Act (CETA) programs will not reduce shortages. However, individuals who complete these programs do qualify for entry into employer training programs and many employers prefer to enroll individuals who have completed an appropriate vocational education or CETA program. Because machinists are expected to have excellent job prospects through the 1980's, earnings are above average, and unemployment rates are low, expansion of these programs is appropriate. However, the major impact of this action will be to improve the quality of the individual entering employer training programs, rather than increasing their number. □

Table 4. Employment in skilled machining occupations, 1980 and projected 1990

[Numbers in thousands]

Occupation	1980 employment	Projected 1990 employment		
		Low trend	High trend I	High trend II
Total, all skilled machining occupations	791.4	910.4	1,023.2	958.2
Job and die setters, metal	93.3	112.5	124.2	114.5
Diesetters	4.3	5.2	5.8	5.4
Machine toolsetters, metal	55.5	65.9	73.7	67.2
Setters, molding and coremaking machines	1.3	1.9	1.9	1.9
Punch press setters, metal	19.2	23.3	25.9	23.9
Shear and slitter setters	5.5	6.6	7.2	6.7
Setters, plastic molding machine	7.4	9.6	9.8	9.4
Machinists	304.3	352.2	390.8	386.3
Layout markers, metal	21.3	24.3	27.2	24.8
Machinists	281.9	326.7	362.3	335.4
Moldmakers, pottery	1.1	1.2	1.4	1.3
Tool and die makers	170.3	184.3	212.2	188.7
Tool-and-die makers	162.8	175.7	202.5	180.7
Diesinkers	3.1	3.4	3.9	3.5
Instrument makers	4.3	5.1	5.7	5.1
Machine-tool operators, combo	170.7	199.9	226.2	205.9
Machine-tool operators, numerical control	52.7	61.2	69.9	62.8

[1] The value of consistency in data collection programs is recognized by the Federal Government. In 1980, the Office of Management and Budget issued the Standard Occupational Classification (SOC) which is to be used by all Federal agencies in collecting occupational data. Federal statistical data therefore will become more compatible throughout the 1980's, as agencies convert to the SOC.

[2] Data from the Current Population Survey are not presented for the years prior to 1972 because the data are not comparable.

The Anatomy of Price Change

Reconciling the CPI and the PCE Deflator: first quarter 1982

JULIE A. BUNN AND JACK E. TRIPLETT

This reconciliation of the Federal Government's two major inflation measures—the Consumer Price Index (CPI), published by the Bureau of Labor Statistics, and the Implicit Price Deflator for Personal Consumption Expenditures (PCE Deflator), produced by the Bureau of Economic Analysis—extends the data through the first quarter of 1982.[1]

Reconciling period-to-period changes. For only the second time in the past 3 years, the Consumer Price Index for All Urban Consumers (CPI-U) rose more slowly than the comparable PCE price measure (the "PCE: Chain-Weight" index)[2] in the first quarter of 1982 (table 1). The most recent quarter is the first time that all three elements—differences in the measurement of housing costs, differences in weighting, and the effect of "all other" factors—of the reconciliation operated to slow the CPI-U relative to the "PCE: Chain-Weight" index.

For the second quarter in a row, the CPI-X1, the version of the Consumer Price Index which approximates a "rental equivalence" measure of housing identical to that employed in calculating the PCE Deflator, increased at a faster rate than the CPI-U. Thus the "housing effect" in table 1 was negative (meaning that, in the most recent quarter, the treatment of housing has contributed to the PCE measure rising faster than the CPI-U).

For the third quarter in a row (and contrary to what is usually expected) the "PCE: Chain-Weight" index, which draws its weights from the immediately preceding period has risen more rapidly than an index based on the same price data, but using 1972 weights.[3] This creates a negative "weighting effect" in table 1.

Finally, the "all other" effect, which measures the influence of compilation and computational differences other than the drawing of weights from different periods and the treatment of owner-occupied housing, continues the first quarter behavior of previous years, but stands out as the largest negative "all other" effect in more than 3 years. Differing seasonal adjustment methods account for part of the "all other" effect.

The most striking result from table 1 is the emergence of negative values for the weighting effect. It is usually expected that an index that uses 10-year-old weights will rise somewhat more rapidly than one that uses recent or current weights, and the weighting effect bore out this presumption for earlier periods (even though weights have never contributed very much to the difference in CPI and PCE movements). In the seven quarters since mid-1980, however, the weighting effect has taken on its expected positive sign in only one quarter (1981–I); in three other quarters, different weighting periods made no difference in the index measurement,

Table 1 "Reconciliation" of annual and quarterly percent changes in the CPI-U and the Personal Consumption Expenditure price measures, 1980 to 1982–I

Difference	1980	1981	1981[1]				1982
			I	II	III	IV	I
CPI-U[2]	13.5	10.4	11.0	7.8	11.8	7.7	3.2
PCE: Chain-Weight[3]	10.6	9.0	10.3	6.5	8.7	7.4	5.7
Total difference[4] (CPI-U minus PCE: Chain-Weight).	2.9	1.4	0.7	1.3	3.1	0.3	−2.5
Housing treatment[5]	2.3	0.9	0.4	0.5	2.7	−0.5	−1.3
Weighting effect[6]	0.4	0.1	0.6	0.0	−0.5	−0.2	−0.5
"All other" effect[7]	0.2	0.4	−0.3	0.8	0.9	1.0	−0.7

[1] Owing to changes in seasonal adjustment factors, the quarterly figures, seasonally adjusted annual rates, may differ slightly from those which appeared in table 1, p. 43, January 1982, *Monthly Labor Review.*

[2] Annual and quarterly changes in the CPI-U are taken from tables provided by the Office of Prices and Living Conditions, Bureau of Labor Statistics. The changes are compiled from 1967 based indexes.

[3] Data for the "PCE: Chain-Weight" were obtained from the Bureau of Economic Analysis, U.S. Department of Commerce.

[4] CPI-U minus "PCE: Chain-Weight" equals the sum of "housing treatment", "weighting", and "all other" effects.

[5] Change in CPI-U minus change in CPI-X1. See September 1981 *Monthly Labor Review,* p. 21, for fuller explanation. Source of CPI-X1 data is same as footnote 2.

[6] Change in "PCE: 1972-Weight" minus change in "PCE: Chain-Weight." See September 1981 *Monthly Labor Review,* pp. 8-9, for fuller explanation. Data source for "PCE: 1972-Weight" changes is same as for footnote 3.

[7] Change in CPI-X1 minus change in "PCE: 1972-Weight." See September 1981 *Monthly Labor Review,* p. 6, for fuller explanation.

Julie A. Bunn is an economist in and Jack E. Triplett is assistant commissioner of the Office of Research and Evaluation, Bureau of Labor Statistics.

while in the three most recent quarters values for the weighting effect have negative signs, reflecting the fact that the index with the most recent weights has registered the larger increase.

Reconciling cumulative changes. Table 2 presents a cumulative reconciliation of the CPI-U and the PCE Deflator (or PCE: Current-Weight), from 1972 to the first quarter of 1982. This table continues the cumulative comparisons of previous reconciliation articles. ☐

Table 2. "Reconciliation" of the CPI-U and the Personal Consumption Expenditure price measures: cumulative percent change from 1972 to the date shown

Difference	1980	1981	1981[1] I	1981[1] II	1981[1] III	1981[1] IV	1982 I
CPI-U (1972 = 100)[2]	197.0	217.4	210.3	214.3	220.4	224.6	225.9
PCE Deflator (1972 = 100) (Current-Weight)[3]	178.9	193.8	188.5	191.5	195.7	199.4	201.8
Total difference							
(CPI-U minus PCE Deflator)[4]	18.1	23.6	21.8	22.8	24.7	25.2	24.1
Housing treatment[5]	11.7	14.5	13.3	13.7	15.4	15.5	14.8
Weighting effect[6]	5.4	7.2	7.3	7.4	7.2	7.0	7.4
"All other" effect[7]	1.0	1.9	1.2	1.7	2.1	2.7	1.9

[1] Owing to changes in seasonal adjustment factors, quarterly figures may differ slightly from those which appeared in table 2, p. 44, January 1982, *Monthly Labor Review.*

[2] Annual data for the CPI-U were computed by the Office of Research and Evaluation (BLS) from unadjusted monthly data provided by the Office of Prices and Living Conditions (BLS). The quarterly data for 1980 and 1981 were computed by the Office of Research and Evaluation employing seasonally adjusted monthly data provided by the Office of Prices and Living Conditions.

[3] Data for the Implicit PCE Deflator, or "PCE: Current-Weight" index, were provided by the Bureau of Economic Analysis. The data incorporate revisions released in April 1981.

[4] CPI-U minus PCE Deflator equals the sum of "housing treatment", "weighting", and "all other" effects.

[5] CPI-U minus CPI-X1. See September 1981 *Monthly Labor Review*, p. 5, for fuller explanation. Data source for the CPI-X1 is the same as footnote 2.

[6] "PCE: 1972-Weight" minus "PCE: Current-Weight." See September 1981 *Monthly Labor Review*, p. 6, for fuller explanation. Data source for the "PCE: 1972-Weight" is same as footnote 3.

[7] CPI-X1 minus "PCE: 1972 Weight." See September 1981 *Monthly Labor Review*, p. 6, for fuller explanation.

FOOTNOTES

[1] The initial reconciliation and technical basis for the analysis is contained in Jack E. Triplett, "Reconciling the CPI and PCE Deflator," *Monthly Labor Review*, September 1981, pp. 3–15.

[2] As discussed in Triplett, pp. 7, 13–14, the "PCE: Chain-Weight" index is comparable to the CPI-U for the purpose of making period-to-period comparisons, while the PCE Deflator, a Paasche-formula index, is used for the cumulative reconciliation because Paasche-formulas lend themselves to statistical interpretation only when referring back to the base year (in this case, 1972).

[3] See footnote 7 to table 1 and the Triplett, "Reconciling the CPI and PCE Deflator," for information on the computation of the weighting effect.

Technical Note

Labor force data: the impact of the 1980 census

Deborah Pisetzner Klein

The widely publicized national unemployment figures are derived from the Current Population Survey. This survey, conducted by the Bureau of the Census for the Bureau of Labor Statistics, obtains information from approximately 60,000 households each month, making it the largest survey of its type in the world. It provides data on employment and the labor force as well as unemployment, including information on age, sex, race, occupation, and industry.

A sample survey is a cost effective means of obtaining current labor force data. Every surveyed individual, 16 years or older, is classified as employed, unemployed, or not in the labor force, based on the responses to a structured questionnaire focusing on specific activities during the reference week. Because labor force classifications are obtained from the sample households rather than a complete universe, the responses must be transformed from raw survey data into estimates which reflect the target national population—the civilian noninstitutional population 16 years and older. This process has several steps which have been detailed in various technical publications.[1] This article addresses only one aspect of the process—the use of independent population estimates derived and updated from the decennial censuses, which are used to transform the sample data into meaningful statistics.

Population estimates

In a simple example, if information were obtained from a sample of 5 individuals who represent a universe of 100, each response would be multiplied by 20. However, in the CPS, independent population estimates have been established for each of 64 age-sex-race groups. The reason for using separate weights by demographic group is to adjust for the fact that the distribution of the individuals who fall into the sample in any month may differ somewhat from that of the entire Nation in terms of age, race, or sex. Because these characteristics are closely correlated with labor force status, sample estimates are more accurate when weighting is done separately for each age-sex-race group rather than with a single population estimate for the sample as a whole.

Population estimates are derived by taking population counts by age, sex, and race from the preceding decennial census and adjusting them monthly throughout the ensuing decade, taking into account the aging of the population, mortality, and net migration. When the actual counts from the subsequent census are available, they become the new benchmark from which to estimate future population levels. In past decades, there has generally been a small discrepancy between the new benchmark and the population estimate for that period as derived from the previous census. As the Census Bureau changed from one set of population controls to the next, there would be a corresponding break in the various labor force series because they were based on these population estimates.

Historically, the effect of the change from one population base to the next was relatively minor. For example, the net differences resulting from the introduction of the 1970 census-based population estimates to the CPS were about 800,000 for population and 300,000 for labor force and employment. However, the conversion to the 1980 census-based population estimates has an entirely different order of magnitude. When the 1980 census was taken, the resident population estimate based on the extrapolation of the 1970 census was 221.7 million. However, the 1980 census actually enumerated 226.5 million persons. Consequently, the population estimates underlying the CPS—the civilian noninstitutional population 16 years and over—were increased by 3.7 million (on an annual average basis in 1981) expanding the labor force by 2.3 million and employment by 2.1 million.

Data adjustment

The Census Bureau and BLS have historically followed the procedure of introducing population weights based on the new decennial census into the CPS in a single month (at the beginning of a year to avoid distortions to annual average data), and indicating in footnotes and technical articles the presence of a series break.[2] Because of the magnitude of the change, this approach was not suitable this time. Accordingly, the Census Bureau revised its intercensal population esti-

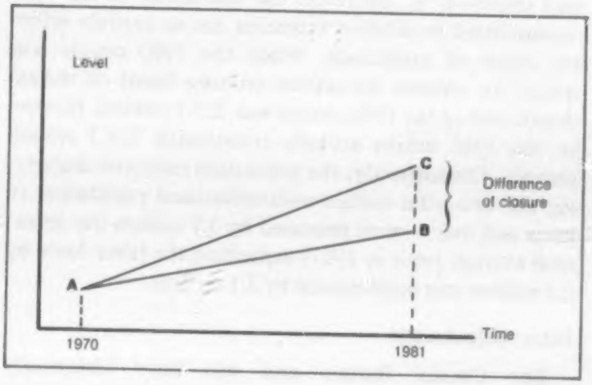
---

Deborah Pisetzner Klein is a senior economist in the Division of Employment and Unemployment Analysis, Bureau of Labor Statistics.

mates and the Bureau of Labor Statistics adjusted many of the more important labor force series in order to avoid sizable discontinuities. Using an estimating methodology developed jointly by BLS and the Census Bureau, the BLS developed revised estimates for some 30,000 labor force series for the 1970's that are consistent with the 1980 census-based population controls as well as the 1970 census.

The revision procedure takes the April 1970 labor force estimates as the last "true" estimate and adjusts each subsequent data cell. The estimated difference in 1981 between each labor force estimate generated by the 1980 census count and the corresponding 1970-based population estimate—called the "difference of closure"—is wedged back in time from December 1980 to April 1970. The procedure takes into account both the distance in time from the 1970 census and the specific size of the difference of closure for each series.[3]

The following simplified diagram may serve to illustrate the procedure. For any labor force series, point A represents the estimate for 1970, point B represents the estimate for 1981 as originally published using the population weights derived from the 1970 census, and point C represents the estimate for 1981 based on the population weights derived from the 1980 census. Thus, line AB represents the 1970–81 trend in the labor force series as originally published, line AC represents the trend after revision, and BC represents the difference of closure. (Had a real labor force series been graphed, AB and AC would not, of course, be straight lines, but rather would follow paths influenced by secular and cyclical developments.)



One reason for revising the data is that many users need to examine trends over time. In fact, one of the strengths of the CPS is that it provides a consistent time series which permits the tracking of cyclical and secular movement among demographic groups.

These labor force revisions are necessarily provisional because the underlying estimates of population for the 1970–80 period are considered preliminary by the Bureau of the Census. Completion of the 1980 census coverage studies and evaluation of the 1970–80 population estimates may cause the Census Bureau to readjust its revised population estimates for the 1970–80 period, which, in turn, may cause the BLS to further revise the CPS labor force estimates.

The wedge procedure is based on the premise that within each group the unexpected population increase took place on a consistent basis throughout the 1970's. Without specific evidence to the contrary, this was the most reasonable assumption to make. While the provisional revision provides a smooth, continuous, and reasonable time series, there are several key questions to consider in determining whether the existing wedge procedure will remain the most appropriate. Studies that could aid in this determination include comparisons of 1970 and 1980 census coverage; evaluation of any estimates of undercount in the 1980 census and how they may differ by age, sex, and race from previous censuses; as well as estimates of the number of illegal aliens counted in the 1980 census and judgments about how long such persons have been living in the United States.[4]

Revised labor force data are being issued by the Bureau of Labor Statistics in several steps. More than 350 series of revised monthly seasonally adjusted data were published in the February 1982 issue of *Employment and Earnings*, which also contained revised annual averages for major estimates back to 1970. The March 1982 issue of *Employment and Earnings* contained 62 tables of 1981 annual averages, some including comparisons with 1980, on a revised basis. (Annual averages for 1981, prior to revision, were published in the January 1982 issue and, thus, are available for comparison.) In terms of the *Monthly Labor Review*, the March 1982 issue was the first to contain revised data. In late 1982, BLS is scheduled to publish a data book with 176 tables containing nearly 15,000 data series on a revised basis. In the meantime, many series of both actual and seasonally adjusted data may be obtained from the BLS upon request. Table 1 provides labor force, employment, and unemployment estimates both before and after revision for the 1970–81 period.

While all data series were subject to revision, the underlying population adjustments caused significant changes to only those series that measured levels or counts. Labor force series which are expressed in terms of percentages—such as the unemployment rate, the participation rate, and the employment-population ratio —were largely unaffected by the revision process. This is because the population adjustments generally had the same proportionate effect on the numerator and the denominator used to derive the percentage. Small changes occurred because of rounding differences and where

Table 1. Employment status of the noninstitutional population using 1970 and 1980 census based population estimates, 1970–81

Year	Civilian labor force		Employed		Unemployed		Unemployment rate

changes in the demographic composition of a group affected larger aggregates.

Revised labor force growth

Compared with the data as originally published, the revised data indicate, of course, a faster pace of labor force growth over the past decade. According to originally published data, the labor force grew by 24 million, or 29 percent, during the 1970–81 period; as revised, the increase was 26 million, or 31 percent. (See table 2.) In terms of employment levels, the comparable rates of growth were 25 percent prior to revision and 28 percent afterwards.

The adjustment was not evenly distributed among the various demographic groups. The 1970–81 labor force growth for men was revised upward by more than 10 percent for every age group through 44 years, but the revised labor force levels were actually lower for men 45 to 54 years of age. Women showed smaller increases until the older age categories, where there were very large changes for 55- to 64-year-olds (31 percent) and those 65 and over (18 percent). In general, the share of workers accounted for by persons under 35 years of age increased with the revised data.

Because of the adjustment methodology, these revised growth patterns are a direct result of the patterns of labor force revisions. Labor force estimates for 1981 are, on average, 2.1 percent higher using the 1980 census-based population estimates. About 70 percent of the 2.3 million increase occurred among persons 20 to 34 years of age, whose "corrected" labor force size was 3.7 percent higher than originally estimated. (See table 3.)

Under the revised system, the number of black workers was 2.6 percent higher in 1981 and the age distribution of the incremental increase was even more skewed toward those under age 35. Unlike the situation for whites, for whom the increments for men and women were about the same, the overall increase in the black labor force was higher for women. Furthermore, the age patterns by sex are quite different. The upward revisions in the black male labor force occurred entirely among persons under 45 years of age. For black women, the gains were spread more widely throughout the age spectrum. This is based upon the fact that, according to the 1980 census findings, the population of black men under age 45, as brought forward from the 1970 census, had been underestimated; black women had also been underestimated but to a lesser degree than these black men. The large differences in the population estimates of black men under age 45 are apparently the result of substantial improvements in the completeness of coverage for this group in the 1980 census. Among black women, the improvements in census coverage in 1980 were more evenly distributed across the various age groups.[5]

The effect of the revision in CPS data was particularly sharp for persons of Hispanic origin.[6] The overall increase in their population estimate was 3.8 percent, about twice the adjustment for whites. The labor force adjustment was not very different for men and women of Hispanic origin, and there was no particular pattern to the adjustments by age. The largest increase occurred among those 20 to 34 years of age, but increases for persons 55 years and older were also larger than average. Within the Hispanic population, adjustments were largest for persons of Cuban origin and smallest for persons of Puerto Rican origin.

Data for *all* published race and ethnic groups are available only since 1973. During the 1973–81 period, the fastest labor force growth was registered for Hispanics, whose population grew dramatically over the period. Based on revised data, the labor force increase was 63 percent during the 8-year period; prior to revision, the growth was estimated to be 60 percent. Despite the sharp increase, the Hispanic share of the total labor force only moved from 4 to 5.5 percent over the period, using either revised or unrevised data.

The black labor force grew faster than the white, but not nearly as fast as the Hispanic labor force. Revisions raised black labor force growth from 22 to 23 percent between 1973 and 1981. Over the same period, white labor force growth had been 19 percent prior to revision and 20 percent subsequently. □

——*FOOTNOTES*——

[1] The most comprehensive discussion of the estimation procedure is included in *The Current Population Survey: Design and Methodology*, Technical Paper 40 (Bureau of the Census, 1977), ch. 5. A summary description is included in the Explanatory Notes of each issue of *Employment and Earnings*, published monthly by the Bureau of Labor Statistics.

[2] For an explanation of the procedures used following the 1970 census, see Gary M. Shapiro and Marvin M. Thompson, "Revisions in Current Population Survey," *Employment and Earnings*, February 1972, pp. 6–9.

[3] For a more technical description of the procedures in this adjustment process, see Kenneth D. Buckley, Jennifer Marks, and Ronald J. Statt, "Revisions in the Current Population Survey Beginning in January 1982," *Employment and Earnings*, February 1982, pp. 7–15.

[4] For the first 1980 census coverage study, see Jeffrey S. Passel, Jacob S. Siegel, and J. Gregory Robinson, "Coverage of the National Population in the 1980 Census by Age, Sex, and Race: Preliminary Estimates by Demographic Analysis," *Current Population Reports*, Series P-23, No. 115 (Bureau of the Census, March 1982).

[5] Ibid.

[6] It should be noted that the estimates of the Hispanic origin population are not based on independently developed controls specifically for this group. Rather, they arise from the weighting process as a result of individual responses to a question on ethnic origin and the age-sex-race estimates.

Family Budgets

Final report on family budgets: cost increases slowed, autumn 1981

Rising personal income taxes, social security deductions, transportation, and homeowner costs contributed to the increases in the three hypothetical budgets for a four-person family. In autumn 1981, the United States urban average budget costs were $15,323 at the lower level, $25,407 at the intermediate level, and $38,060 at the higher level (table 1). From autumn 1980 to autumn 1981, the lower budget rose 9.1 percent, the intermediate, 9.8 percent, and the higher, 10.6 percent (table 2). The increases in 1981 were approximately 3 percentage points less than those in 1980, reflecting smaller increases in food and personal income taxes.

This report is the final release of the urban four-person family budget data. The expenditure data on which the budgets are based are now 20 years old and continuation of the program would require a revision of concepts, more current expenditure data, and extensive collection of price data, for which funding was not available. Therefore, the program was eliminated in compliance with the recent overall budget reduction.

Consumption costs. Consumption costs rose by 7.3 percent at the lower level, and 7.5 percent at both the intermediate and higher levels between autumn 1980 and autumn 1981. Among consumption components, transportation costs showed the largest increases at all three levels. Transportation costs also rose sharply in the two previous years from autumn 1978 to autumn 1979 and from autumn 1979 to autumn 1980. Medical care costs also showed large increases from 1980 to 1981.

Table 1. Annual budgets for a four-person family at three levels of living, urban United States, autumn 1981

Component	Lower	Intermediate	Higher
Total budget	$15,323	$25,407	$38,060

Social security	17.6	19.3	23.9
Personal income taxes	19.4	17.5	17.9

[1] Includes only rental housing in the lower budget.

[2] On the assumption that the home was purchased 6 years ago, these costs reflect changes in purchase prices and mortgage interest rates from 1974 to 1975 and changes in property taxes, insurance, fuels and utilities, and repairs and maintenance from 1980 to 1981.

Personal income taxes. The budgets include estimated 1981 Federal, State, and local tax payments. The large increases in taxes, approximately 19 percent at the lower level and 18 percent at both the intermediate and higher levels, are a result of increasing consumption costs and "bracket creep" under the Federal progressive tax system and that of many States. Although tax increases were quite large, they were approximately 10 percentage points less than in 1980 at the lower level and approximately 7 percentage points less at both the intermediate and higher levels. This was because of more moderate price increases for consumption items and the small, initial reduction in Federal income tax rates in 1981. While the percentage tax increase was highest for the lower budget, the effect of the increases was more pronounced at the intermediate and higher level because taxes constitute a proportionally larger share of these budgets.

Social security deductions. While Federal income tax increases were lower, social security deductions were higher in 1981. The employee payroll deduction rate was increased from 6.13 percent to 6.65 percent, and the earnings ceiling on contributions was raised from $25,900 to $29,700. As a result, deductions rose 18 percent at the lower level, 19 percent at the intermediate level, and 24 percent at the higher level.

Housing. Housing increased by 8.0 percent from autumn 1980 to autumn 1981 in the lower budget which includes only renter costs. Both renter and homeowner costs are included in the intermediate and higher budgets and these costs rose by 8.6 and 8.7 percent, respectively. For the homeowner component, large increases in fuel and utilities were offset somewhat by modest increases in mortgage interest costs.

Description of the budgets. The family budgets represent the costs of three hypothetical lists of goods and ser-

[1] The family consists of an employed husband age 38, a wife not employed outside the home, an 8-year-old girl, and a 13-year-old boy.

[2] Housing includes shelter, housefurnishings, and household operations.

[3] Renter costs include average contract rent plus the cost of required amounts of heating fuel, gas, electricity, water, specified equipment, and insurance on household contents.

[4] Homeowner costs include interest and principal payments plus taxes, insurance on house and contents, water, refuse disposal, heating fuel, gas, electricity, specified equipment, and home repairs and maintenance cost.

[5] The average costs of automobile owners and nonowners in the intermediate budget were weighted by the following proportions of families: Boston, New York, Chicago, and Philadelphia 80 percent for owners, 20 percent for nonowners; Baltimore, Cleveland, Detroit, Los Angeles, Pittsburgh, San Francisco, St. Louis, and Washington, D.C., with populations of 1.4 million or more in 1960, 95 percent for automobile owners and 5 percent for nonowners; all other areas, 100 percent for automobile owners.

[6] In total medical care, the average costs of medical insurance were weighted by the following proportions: 30 percent for families paying full cost of insurance; 26 percent for families paying half costs; 44 percent for families covered by noncontributory insurance plans (paid by employer).

[7] Other family consumption includes average costs for reading, recreation, tobacco products, alcoholic beverages, education, and miscellaneous expenditures.

[8] As defined in 1960-61. For a detailed description of these and previous geographical boundaries, see the 1967 edition of *Standard Metropolitan Statistical Areas*, prepared by the Office of Management and Budget.

[9] Places with population of 2,500 to 50,000; data for some previously shown are no longer available.

vices that were specified in the mid-1960's to portray three relative standards of living—described as lower, intermediate, and higher. These budgets are for a precisely defined urban family of four: a 38-year-old husband employed full time, a wife not employed outside the home, a boy age 13, and a girl age 8. Average inventories of clothing, housefurnishings, major durables, and other equipment are included for each budget level. The budgets pertain only to an urban family with these specified characteristics; no budgets are available for rural families. Also, the budgets are not intended to represent a minimum level of adequate income or a subsistence level of living, nor do they indicate how families do or should spend their money.

The 1981 consumption budgets were estimated by applying price changes for individual areas from autumn 1980 to autumn 1981, as reported in the Consumer Price Index for Urban Wage Earners and Clerical Workers, to the appropriate autumn 1980 budget costs for each main class of goods and services. ☐

Is the compressed workweek too compressed?

The compressed workweek, usually involving 4 working days with Friday or Monday off, is something of a misnomer in that it also means an elongated workday of 10 hours. There has been more experience with this concept in the United States; European workers, on the other hand, have shown little interest.

The compressed workweek was developed in the United States in the late 1960's, and has been tried mainly by smaller, nonunion employers. Acceptance has not been overwhelming, having leveled off at about 2 percent of the labor force, according to the Bureau of Labor Statistics. The failure rate of the compressed workweek is quite high, in sharp contrast to flexitime experiments. Many companies seem to have tried it; yet every survey shows a high percentage soon reverting to the 5-day week.

Native Americans in the labor force: hunting for an accurate measure

JUDITH KLEINFELD AND JOHN A. KRUSE

The concepts used nationally to assess labor force participation are considered to be inappropriate for Native American population groups. The fundamental issue concerns the measurement of unemployment. The Current Population Survey (CPS) defines an unemployed person as someone who has no employment, is available for work, and has engaged in some specific jobseeking activity within the past 4 weeks. As the American Indian Policy Review Commission points out, in many Indian reservations and isolated Native villages, few jobs are available.[1] In these small communities the informal communications network provides excellent information on new employment opportunities. Many Indian and Eskimo adults do not actively seek work in the conventional sense because they are well aware that no work is available. To exclude these individuals from the labor force results in a serious underestimation of Native American unemployment and the available labor pool. Moreover, this problem is not merely a technical issue of measurement. Federal and State funds are allocated to regions on the basis of such employment statistics.

While the knowledge that no jobs exist may cause significant members of Native Americans not to be counted as members of the labor force, there is also evidence to suggest that many Native Americans in fact drop out of the labor force intermittently in order to meet community and family obligations, or to pursue other activities such as hunting and fishing. For example, Harland Padfield and John van Willigen carefully studied the activity patterns of a sample of 300 Papago men.[2] They found that 15 percent were "voluntarily idle" in midsummer.

Attitude surveys also suggest substantial variability in Native Americans' work schedule preferences. According to some surveys, the majority of Indians and Eskimos prefer long-term jobs, suggesting that it is teachers and employers who incorrectly overestimate preferences for seasonal work.[3] However, these studies, as well as other research, suggest considerable variability in preferences for year-round and part-year wage work, not only among different Native American population groups but also among individuals in the same group.[4] Therefore, the measurement problems associated with unemployment among Native Americans are not limited to the discouraged worker effect; they also stem from real desires not to work for wages during part of the year.

To overcome these problems, agencies and researchers concerned with Native American populations have used a variety of alternative concepts and measurement approaches to assess unemployment. The Bureau of Indian Affairs, for example, considers any Native adult who does not hold a wage job to be "unemployed." Agency personnel roughly estimate unemployment in some rural Native communities and reservations to be as high as 50 to 80 percent. The American Indian Policy Review Commission, suspecting that census figures underestimate and Bureau of Indian Affairs figures overestimate Native American unemployment, suggested that the 1980 census questions on unemployment should be adapted to the situation of American Indians.[5] The Commission recommended that Indians be asked, "When job opportunities occur, do you seek them?"

The 1980 Census Supplementary Questionnaire for Indians, however, did not follow this recommendation. The question on unemployment asks, "Of the weeks not worked in 1979, how many weeks was this person actively looking for work or on layoff from a job?" Previous questions ask how many weeks the person worked in 1979 and the main reason the person worked fewer than 50 weeks. However, respondents have no socially acceptable way of indicating that they prefer a lifestyle combining intermittent participation in the wage economy with non-wage activities, such as subsistence hunting and fishing. Such a response would be placed in the category "did not want work," which has negative connotations, particularly for men without obvious home responsibilities.

Without information on the size of the intermittent worker effect, statistics on Indian and Eskimo employ-

ment patterns are difficult to interpret. For example, Benjamin Taylor and Dennis O'Connor, in a study of five Indian reservations in the Southwest, point out that "seasonal or irregular work characterizes a significant part of reservation labor, ranging from 27 percent of the working-age Zaguna tribe to 55 percent of the Fort Apaches over 16 years of age."[6] However, it is not clear to what extent these patterns are the result of personal preference and to what extent they are caused by lack of jobs and requisite skills.

Alaskan research

This paper discusses three Alaskan studies concerned with measuring unemployment in Native American groups. These studies suggest the importance of both a "discouraged worker" and an "intermittent worker" effect in understanding Native American employment patterns. Standard national definitions of unemployment substantially underestimate the proportion of Natives who want work and are available for work. However, our research also suggests that average labor force participation rates, at least among men, may remain substantially below national norms even when high-paying jobs at a variety of skill levels are available.

The first study was conducted in January 1977.[7] The Alaska Legislature, believing that official employment statistics seriously understate unemployment in rural Native communities, directed the State Department of Labor to survey "real" unemployment in the Lower Yukon-Kuskokwim Region. Income levels in the Eskimo communities in this isolated area are among the lowest in Alaska, and job opportunities are extremely limited. Of available jobs, 44 percent are in government. However, the region also has a strong noncash economy based on subsistence fishing and hunting. In addition, commercial fishing, trapping, and crafts are important sources of cash income, although no statistics are available on employment in these occupations.

Bilingual Eskimos interviewed 86 percent of the working-age adult population (1,412 respondents) in nine villages. They used a one-page form patterned on the CPS. As in the CPS, one set of questions classified individuals as "unemployed" if they were not working and had "been looking for work during the past four weeks." However, the villagers were also asked about desire for work. "Does the person want a regular job now, either full or part-time?" Under the conventional CPS definition, the unemployment rate in January 1977 was 24 percent. Under the broader definition, it was 48.8 percent.

While national surveys also yield higher jobless rates when "discouraged workers" are included, these results support the view that unemployment among Natives is seriously underestimated. However, the specific survey question used has some limitations.

First, there is the problem of respondents presenting themselves to an interviewer in a favorable light. Village Eskimos in remote communities are well aware of the majority culture's work ethic, whether or not they personally subscribe to it. Without an obviously acceptable reason, such as child care responsibilities or poor health, they might have been reluctant to tell the interviewer that they did not want to work at the time of the survey.

Second, the question does not cover desired duration of employment. In another household survey, which included some of the same communities, most of the 344 respondents indicated that they preferred to work only certain months of the year. Those who wanted part-year work generally did not want to be employed in the spring or fall, seasons of intense subsistence activity.[8] Indeed, some Eskimos may view wage work as a secondary activity, a means to supplement hunting and fishing. Thus, asking whether the individual wants a "regular" job may miss a critical cultural difference in labor force behavior.

North Slope boom

In the second study, funded by the National Science Foundation, we examined the response of the Inupiat to the new high paying job opportunities on the North Slope in 1977.[9] A previous study of Native employment directly associated with the trans-Alaska pipeline project found that many Natives had worked for only 8 weeks or less despite the high pay.[10] During informal interviews, Native respondents cited work camps located away from home, the heavy 10-hour, 7-day workweek, bigotry against Natives by white coworkers, and alleged poor use of Native workers by the companies, as disincentives to longer employment tenure.[11]

On the North Slope, however, oil and gas development created a situation which eliminated or modified many of these perceived barriers to long-term employment. The jobs resulted not so much from direct oilfield activities at Prudhoe Bay as from the formation of an Inupiat government, the North Slope Borough, in 1972. The borough, encompassing eight Inupiat villages and a population of about 4,000, levied property taxes on the Prudhoe Bay oil complex. Revenues grew from less than $1 million in 1973 to about $57 million in 1977. The borough transformed these tax revenues into jobs adapted to contemporary Inupiat lifestyles. It launched a $511 million capital improvements program, which resulted in large numbers of skilled and unskilled construction jobs. Borough government and school district operations also employed large numbers of white-collar workers. By 1977, the borough alone employed about 800 workers in administration, education, and construction.

The government established a strong local hire program and was willing to absorb substantial cost overruns to employ local Inupiat. To minimize conflicts between wage work and subsistence, the borough granted leaves of absence for subsistence activities and was tolerant of absenteeism. It paid high wages, with construction pay matching the wage scales established during the building of the trans-Alaska pipeline. The average wage of Inupiat adults in 1977 was almost $500 per week, and about 25 percent received paychecks of $800 or more. Yet, borough jobs did not require workers to leave home, give up subsistence activities, cope with bigotry, or deal with an uncomfortable, non-Native environment.

The borough did not succeed in making jobs available to all Inupiat adults in each of the eight villages during the entire year. However, in certain situations, such as in Barrow (the large regional center), jobs were readily available to anyone who wanted wage work during the summer construction season.

The North Slope study examined the question—under these unusually favorable labor market conditions did the labor force participation rate of Inupiat men and women approach national norms? Or did special cultural factors result in lower labor force participation despite the availability of good jobs and the presence of loosely structured work rules?

Inupiat interviewers conducted a household survey in Barrow and five smaller communities in late 1977. We had randomly selected one adult from each village household and one adult from a 50-percent sample of Barrow households. The final sample consisted of 290 persons, 75 percent of the adults contacted, and represented 21 percent of the adult population. In our labor force analysis, we excluded persons age 16 to 18 and 55 and older so that cultural differences in school attendance and retirement ages would not affect comparisons with national labor force patterns.

Those interviewed were asked for a work history from October 1976 to September 1977. Persons who did not hold any paying job during the year were asked whether there were special reasons that prevented them from working. To measure monthly unemployment the survey asked, "Were there months between October 1976 and September 1977 when you wanted a job and didn't have one? (If yes) What months were they?" This measure of unemployment was, of course, a broad definition, which counted a person as "unemployed" if he or she stated a desire for wage work regardless of specific jobseeking activity.

In analyzing the data, it quickly became apparent that many Inupiat did not say they wanted wage work during all the months they did not work. Some were nonwage earners, whose family responsibilities or health problems prevented them from taking employment. However, many were intermittent workers who worked at wage jobs part of the year. In addition, when asked about work schedule preferences, slightly more than half of both men and women said they wanted some form of part-year work.

This preference for part-year work was even stronger among North Slope Inupiat high school students, particularly male students.[12] In this small survey, our question on work preferences contained a socially acceptable alternative to year-round wage work ("After you have finished your schooling, do you want a year-round job or to work only part of the year so you can hunt and fish a lot, or don't you want a job?"). None of the students stated they didn't want a wage job at all. However, of the 75 male students, 69 percent preferred a part-year job compared to 41 percent of the 99 female students.

When we measured annual average labor force participation,[13] Inupiat adult women approached national norms, particularly the young women. However, Inupiat male labor force participation at all ages was far below national norms.

The major reason for the lower male labor force participation was that most men were blue-collar workers. When particular construction projects ended in their villages, they were laid off. Substantial layoffs occurred in the winter of 1976–77, when the borough cut back on its construction program because of financing difficulties. However, intensive construction work resumed in the summer of 1977. This increase in job opportunities led to a dramatic increase in male labor force participation, which rose from a low of 47 percent in November 1976 to a high of 74 percent in September 1977.

Yet, even when good job opportunities were abundant, Inupiat male labor force participation remained well below national norms. In Barrow, for example, labor force participation of Inupiat men age 18–55 peaked at only 76 percent in the summer of 1977. Of the 24 percent who were not in the labor force, just 10 percent were nonwage earners and most of these had health problems. The remainder were intermittent workers who chose not to work during the month.

In short, the North Slope study suggests that the major factor influencing Native American labor force participation is indeed the availability of good jobs. Yet, even under highly favorable circumstances, cultural preferences result in labor force participation rates below national norms, at least among men.

Although our North Slope research results suggested that the number of intermittent workers is significant, we could not precisely measure the number of such workers. We had asked retrospectively what months individuals were without work but wanted it. However, people may have forgotten specific months. We attempted to remedy this problem in a subsequent study by including a question which asked explicitly whether individuals did not want work in particular months.

Regional surveys

In 1979, we cooperated with several Federal and State agencies to conduct a broad survey of recreation, employment, and other community issues in randomly sampled households in the Interior, Southcentral, and Southeast regions of Alaska. Each regional survey included the urban center, surrounding small Native and other communities, and rural Native villages. The Native sample consisted of 335 respondents representing Eskimo, Aleut, Athabascan, and Tlingit cultural groups.[14]

The survey questions concerning employment were essentially the same as in the North Slope study. However, in addition to asking each respondent which months during the previous year "did you want a job but did not have one," respondents were also asked, "Which, if any, months between April 1978 and March 1979 did you decide not to work?" Thus, the decision to withdraw temporarily from the labor force was measured directly rather than being inferred as a residual category.

The results show that rural Natives specifically did not want to work during an average of 1.4 months of the year. The particular months specified varied by region. In the Interior, peak withdrawal occurred in August (17 percent); in Southcentral, the peak was in October (9 percent); and in Southeast, it was January through March (8 percent). However, even with these explicit answers, there remained a large residual of Natives who were not working at wage jobs and who stated neither that they wanted work nor that they did not want work in a particular month. This residual ranged from 12 percent in the Interior to 8 percent in Southcentral Alaska. If we assume this group would take work if jobs were available, 29 percent in Interior, 18 percent in Southcentral, and 24 percent in Southeast were unemployed. If we assume this group was not interested in wage work, although reluctant to say so, unemployment rates would drop to 17 percent in the Interior, 10 percent in Southcentral, and 13 percent in Southeast. The use of these series of questions to estimate annual average unemployment results in a bracket around the "true" proportion of Native American unemployment. Whichever estimate is used, it is obvious that serious levels of unemployment exist in these regions.

Thus, even by providing a means for respondents to differentiate between unemployment and temporary withdrawal from the work force, our estimate of unemployment remains imprecise. However, in these Native American population groups the nature of unemployment itself is imprecise. Some adults shift in and out of wage work depending on job availability, immediate need for cash, and what other options exist at the time. It is, of course, possible to develop a series of questions which unambiguously assigns adults to a labor force category each month. Indeed, in an exploratory study, we attempted to ask Native respondents about their activities in the wage and nonwage sectors and whether they wanted employment on a month-by-month basis. This measurement approach, however, worked badly. Native adults resented and resisted having their activities categorized in these ways. Such a survey approach was perceived as too intrusive. It made too obvious the number of months adults were not engaged in some "productive" activity by majority culture definitions.

Conclusions

Taken together, these studies confirm that the standard definition of unemployment results in a serious underestimation of the number of Native Americans who want wage work. The availability of local employment opportunities, or the lack of them, are well known and largely determine whether individuals actively look for work. At the same time, these studies suggest that significant numbers of Native Americans chose to work intermittently in the wage economy, although the proportion of such worker is likely to vary among cultural groups. Both the "discouraged worker" effect and the "intermittent worker" effect makes it quite difficult to measure Native American labor force participation.

We can offer no simple solution to the problem of how to measure unemployment in Native American population groups heavily involved in a nonwage as well as a cash economy. Two general points emerge from our analyses:

- Questions designed to measure unemployment among transitional Native groups should present a choice between wage work and socially prestigious alternatives in the local cultural situation. Native Americans are aware of the majority culture work ethic and can be reluctant to indicate that they are not employed and do not want wage work.
- Studies of Native American labor force patterns should recognize the possibility of preferences for part-year versus year-round work (in addition to part-time versus full-time jobs) and should include questions to assess during how much of the year and at which times individuals want wage work.

The specific measurement approach we have developed (asking adults which months they were employed, which months they wanted work, and which months they did not want work) results in a range, rather than a single estimate, of unemployment. About 10 percent of Native adults who are not working in particular months do not place themselves in the alternative work-do not want work categories. This ambiguity, however, may reflect the actual vagueness of unemployment among individuals who maintain a lifestyle combining economic activity in both the modern and traditional sectors in the context of extended families who provide mutual economic support. It is perhaps unrealistic to expect that precise answers to questions on unemployment can be found in this cultural context. ☐

Major Agreements Expiring Next Month

This list of collective bargaining agreements expiring in August is based on contracts on file in the Bureau's Office of Wages and Industrial Relations. The list includes agreements covering 1,000 workers or more.

Employer and location	Industry	Labor organization[1]	Number of workers
Alabama Dry Dock and Shipbuilding Co. (Mobile, Ala.)	Transportation equipment	Marine and Shipbuilding Workers	1,200
American Airlines, Ground Service (Interstate)[2]	Air transportation	Transport Workers	12,450
American Standard, Inc., Wabco Construction Equipment (Peoria, Ill.)	Machinery	Boilermakers	1,000
Associated General Contractors of America, Inc., Building Construction Agreement (Alabama)	Construction	Bricklayers; Carpenters; Laborers; Iron Workers; Engineers; Teamsters (Ind.)	8,000
Bowman Transportation, Inc. (Interstate)	Trucking	Steelworkers	2,100
Bucyrus-Erie Co. (Indiana, Pennsylvania, and Wisconsin)	Machinery	Steelworkers	2,000
Cluett, Peabody and Co., Inc., Arrow Co. Division (Interstate)	Apparel	Clothing and Textile Workers	4,600
Eagle Electric Manufacturing Co., Inc. and Eagle Plastics Corp. (New York)	Electrical products	Auto Workers (Ind.)	1,500
Flexsteel Industries, Inc. (Iowa, Pennsylvania, and Texas)	Furniture	Upholsterers	1,000
Gates Rubber Co. (Denver, Colo.)	Rubber	Rubber Workers	2,650
Goodyear Aerospace Corp. (Akron, Ohio)	Transportation equipment	Auto Workers (Ind.)	1,300
Illinois Food Retailers Association, Independent Food Stores	Retail trade	Food and Commercial Workers	4,350
Knitgoods Agreement (Ohio)[3]	Textile	Ladies's Garment Workers	1,050
New York Telephone Company	Communication	Telephone Traffic Union (New York) (Ind.)	8,300
Pittsburgh Forgings Co., Greenville Steel Car Co. (Pennsylvania)	Transportation equipment	Auto Workers (Ind.)	1,000
Publix Shirt Corp. (Interstate)	Apparel	Clothing and Textile Workers	1,000
Sun Harvest, Inc. (California)	Agricultural products	Farm Workers	1,350
Textron, Inc., Fafnir Bearing Division (New Britain, Conn.)	Machinery	Auto Workers (Ind.)	3,200
3M Company, Minnesota Mining and Manufacturing Co. Division (St. Paul, Minn.)	Stone, clay, and glass products	Oil, Chemical and Atomic Workers	1,850
	Government activity	Labor organization[1]	
California: Los Angeles County Building Trades and Skilled Craftsmen	Multidepartment	Los Angeles County Building and Construction Trades Council	1,350
Pennsylvania: Philadelphia Board of Education	Education	Teachers	18,000
Washington: Seattle Police Department	Public safety	Seattle Police Officers Guild (Ind.)	1,050

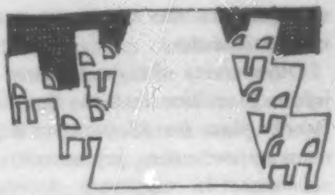
Developments in Industrial Relations



Goodrich pact sets pattern for industry

B.F. Goodrich Co. and the Rubber Workers negotiated a 3-year contract that set a pattern for settlements at Goodyear Tire & Rubber Co. and Firestone Tire & Rubber Co. The terms also affected employees of Uniroyal, Inc., who had earlier agreed to accept the same provisions as in the pattern-setting settlement, modified to the extent necessary to reduce the cost by $18.3 million a year. (See *Monthly Labor Review*, March 1982, p. 47.)

The Goodrich contract did not provide for any specified wage increases, but the employees will continue to receive quarterly automatic cost-of-living pay adjustments calculated at 1 cent an hour for each 0.26-point movement in the Consumer Price Index. The union said the formula would yield about $2.44 in wage increases during the contract term, assuming a 7-percent annual rise in the CPI.

Benefit improvements included a $1.50-increase in the pension rate, bringing it to $16.50 a month for each year of credited service; a $60-a-week increase in the sickness and accident benefit, bringing it to $185; and a 6-month increase in the 24-month period during which laid off employees retain their life and health insurance.

The contract calls for establishment of a medical surveillance program to attain early detection of job-related health problems. The program will be financed by a company payment of 2 cents an hour.

An Early Action Committee will be established to help avert plant closings. The parties also agreed that the Rubber Workers' president will consult with the company president on plant closings and other problems. The agreement applied to 6,700 Goodrich employees at five plants.

About 2,000 workers at the company's industrial products plant in Akron, Ohio accepted a smaller package in return for company assurance that the operation will continue for at least 3 more years. Goodrich also agreed to establish a profit-sharing plan for the workers.

The Akron employees will receive the same benefit improvements as those at the other plants but their pay was cut 27 cents an hour immediately, and will be cut an additional 27 cents in the second and third years if the facility continues to operate at a loss. Also they will not receive any cost-of-living pay adjustments during the entire term, regardless of operating results. Goodrich said that the plant, which once employed 11,000 people, has been losing $1 million a month for the last 2 years.

The Goodyear accord did not provide for a medical surveillance program. The Goodyear settlement covered 16,000 workers at 13 locations and the Firestone settlement covered 10,500 workers at 10 plants.

Harvester accord features profit-sharing plan

International Harvester Co.'s efforts to return to profitability were enhanced when the Auto Workers agreed to a new contract that a company official said, bears a "family resemblance" to the concessions negotiated by General Motors Corp. and Ford Motor Co. (See *Monthly Labor Review*, May 1982, p. 59.)

The Harvester accord, like the two automobile agreements, did not provide for any specified wage increases over its 29-month term, called for 18-month deferrals of each of the first three quarterly cost-of-living adjustments that would have been effective in 1982, and eliminated some paid personal holidays.

The profit-sharing plan adopted at Harvester differed from that in the auto agreements. Union vice president Stephen Yokich said that under Harvester's plan, workers will receive part of every dollar of profit earned by the company during the fiscal years beginning November 1 of 1982 and 1983. (At Ford and GM, workers participate only if profits exceed specified levels.) However, there were no indications that there would be a profit to share. Company chairman and chief executive officer Archie McCardell, who resigned shortly after the settlement, predicted a loss of more than $500 million for the current fiscal year. Harvester lost a total of $790 million during the 2 preceding years. If Harvester shows a profit, and the earnings exceed $300 million in two succes-

"Developments in Industrial Relations" is prepared by George Ruben of the Division of Developments in Labor-Management Relations, Bureau of Labor Statistics, and is largely based on information from secondary sources.

sive quarters, the agreement is subject to reopening on economic issues.

Other terms of the settlement called for Harvester to infuse $6 million into the Supplemental Unemployment Benefit plan; for adoption of a plan to assure employment opportunities, job security, and greater worker involvement in corporate decisions; and for stronger employee protections on potential plant closings and contracting out of work.

According to Yokich, Harvester's management promised union bargainers that the company would become a model of good labor relations and would strive to "absolutely set the standard (in the industry) for goodwill" with its workers. Some industry observers have attributed Harvester's financial problems to the bitter 1979 confrontation between the union and company, which culminated in a 6-month strike, and to adverse economic conditions that also hit other manufacturers of farm and construction equipment and trucks.

The new pact supersedes the balance of the contract scheduled to expire September 30, 1982. About 20,000 active employees at plants in nine states are covered; 10,000 others from the bargaining unit were on layoff. Overall company employment was less than 65,000, compared with 93,000 in 1979, when the previous contract was negotiated.

American Motors, UAW concession accord

Wage concession bargaining continued in the automobile industry, as American Motors Corp. and the Auto Workers negotiated a new contract that featured an Employee Investment Plan, under which the 14,000 workers will lend the company about $110 million by deferring normal wage and benefit provisions. Raymond Majerus, head of the union's American Motors Department, said the loan will provide the company with money needed to develop "a new line of high quality autos." He expects American Motors workers to recoup their losses before the expiration date of the contract, unlike workers at General Motors Corp. and Ford Motor Co. (For an account of GM and Ford concessions, see *Monthly Labor Review*, May 1982, pp. 59–60 and April 1982, p. 62.)

The money will be accumulated by "banking," paid time off and by deferring pay increases:

- The effective date of 3 percent pay increases that would normally have been effective in September of 1982 and 1983 were deferred until January 1985 (a 3-percent increase that would normally have been effective in September 1984 was eliminated);
- The six quarterly automatic cost-of-living adjustments that would have normally been effective in March, June, September, and December of 1982 and in March and June of 1983 will be deferred to December 3, 1984 (however, if the total calculated amounts of these adjustments exceed $1.20 an hour, the excess will be paid on the normal quarterly adjustment date).
- Employees will "bank" 21 days of pay until 1985 by giving up 5 days of holiday or vacation pay in 1982, 8 days in 1983, and 8 days in 1984.
- The effective dates of certain benefits will be delayed for new employees.

The amount that the workers lose by deferring wage increases and "banking" will be repaid, with 10 percent compound interest, beginning in 1985 and concluding not later than 1989, even if the company is operating at a loss.

For repayment purposes, American Motors will allocate an amount equal to either 25 percent of its automotive profits (during the preceding year) or all profit in excess of 4 percent of sales, whichever is greater. If there is no profit, or if the profit is too small for repayment purposes, the union can opt for a formula calling for the company to repay $100 for each of the first 200,000 vehicles and $150 for each additional vehicle produced in the United States and Canada in a year, in addition to 10 percent of company profits.

In return for the concessions, the company agreed to keep the plants open until the September 1985 termination date of the contract, except in the "gravest economic circumstances." The plants are in Toledo, Ohio, and Milwaukee and Kenosha, Wisc. Also, it pledged to conduct all employment cutbacks—except those resulting from reduced sales—through attrition; notify the union 60 days before any major "outsourcing" (contracting out) decisions; apply wage and benefit cost-saving measures to nonunion employees and reduce the number of supervisors; adopt a company-financed legal services plan; and reopen the agreement if more than 300,000 AMC and Renault vehicles are produced or imported in any 6 consecutive months.

The new contract supersedes the balance of an agreement scheduled to expired in September 1983. Currently, Chrysler Corp. is the only "Big Four" automaker left to settle with the UAW in 1982.

Amtrak agreements deviate from pattern

In the rail passenger service industry, Amtrak reached agreements with six unions for 10,000 employees and bargaining was continuing with nine other unions for 7,000 other workers. Union officials said that the accords were similar to the pattern settlements negotiated by 10 rail unions in 1981 (see *Monthly Labor Review*, January 1982, p. 24) except for several provisions that were included in the Amtrak agreements because of congressional mandates for increased efficiency. According to an Amtrak official, the deviations from the pattern included somewhat smaller pay increases, changes in work rules, reductions in overhead, and changes intended to improve "on time performances." The unions involved in the settlements were the Maintenance of Way Employees; Railway and Airline Clerks; Electrical Workers (IBEW); Boilermakers and Blacksmiths; Machinists; and the Transport Workers and Railway Carmen, who bargain jointly.

High court finds two schools guilty of job bias

In a case involving two public school systems, the Supreme Court ruled that a 1972 law banning discrimination in federally financed educational programs also applies to school employment practices. The issue arose when the former Department of Health, Education and Welfare attempted to withhold funds from the schools, located in North Haven and Trumbull, Connecticut, to force them to comply with the 1972 law banning discrimination in education. Initially, a Federal judge had held that the law did not apply, but an appeals court backed the Federal agency's position, leading the schools to appeal to the Supreme Court.

Writing for the 6-member majority, Justice Harry Blackmun said that while the law does apply to school employment discrimination, the fund cutoff must be limited to the particular program or part of a program actually receiving the aid. This means that the lower court must determine if the funds were so diffused throughout the two school systems that the cutoff should apply to the entire systems.

Company ordered to pay value of concessions

A Federal district judge ruled that the Singer Co. must pay damages to Local 461 of the International Union of Electrical Workers if it closes its Elizabeth, N.J., plant. The local had agreed to labor cost concessions in 1981 in return for a pledge that the facility would be kept open. (See *Monthly Labor Review*, May 1982, p. 61, for the closing announcement.) Judge Herbert J. Stern found that the contract did not contain a promise that the sewing machine plant would be kept open and that Singer, therefore, has the right to close the plant. However, he ruled that the company was liable for the approximately $2 million value of the concessions to date.

A&P wins concessions in local bargaining

The Great Atlantic and Pacific Tea Co. was successful in its new strategy of seeking labor-cost concessions in local bargaining, as workers in the Philadelphia area agreed to contract changes that will result in the reopening of "a large number" of stores. A&P had closed about 75 stores in the area during the preceding 12 months. The company adopted the local bargaining strategy after the United Food and Commercial Workers rejected its proposals for companywide concessions. (See *Monthly Labor Review*, June 1982, p. 64.) A&P indicated that it would form a subsidiary, Super Fresh Food Centers, Inc., to operate the reopened stores. Company chairman James A. Wood said the subsidiary would operate under a "unique collective bargaining agreement" that would include "incentives and investment programs" for the union members.

Apartment house workers settle

In New York City, 30,000 employees of 3,500 apartment buildings were covered by a settlement between the Service Employees and the Realty Advisory Board. Wage terms included an immediate raise of $24 a week, a $21-increase in the second year, and $20 in the final year. The cost-of-living adjustment formula was revised to provide for pay increases of 4 cents an hour (formerly 3) for each percentage point rise above 8.5 percent in the Consumer Price Index for New York, N.Y.—Northeastern, N.J.

Benefit provisions included an 11th paid holiday—with individual employees given the choice of selecting Good Friday, Yom Kippur, or the birthday of Dr. Martin Luther King Jr.; and full pay (instead of 70 percent) for unused sick leave.

Insurance companies offer early retirement

Three major insurance companies offered special early retirement inducements to 3,600 employees to help reduce operating costs in the face of a slowdown in sales resulting from increased competition and the economic recession. Two of the companies—Metropolitan Life Insurance Co. and Continental Corp.—indicated that the retirement inducements were an alternative to possible layoffs.

At Metropolitan, the offer applied to 500 workers at its New York City and San Francisco regional headquarters. The workers, most of them in their fifties, were offered payments of up to 1.5 years of salary as an inducement to early retirement. The company also reported that it eliminated 9,000 sales agent jobs through attrition during the last 10 years.

At Continental, 900 of 1,400 eligible employees had already accepted the offer, which included lump-sum payments up to 6 months' pay plus special pension supplements continuing to age 62.

Prudential Insurance Co.'s offer to 1,700 workers included cash payments of up to a year of salary. About

300 to 400 workers are expected to accept the offer. The company said that early retirement would relieve "surplus staffing" and also open promotions to more women and members of minority groups.

Workweek reduced for State employees

Idaho Governor John Evans ordered a 20-percent reduction in the workweek and pay of more than 3,000 State employees to help balance the budget for the fiscal year that ended June 30. The cut lasted 7 weeks and applied only to workers paid from the State's general fund; about 10,000 other workers were not affected. The balance of the $12 million shortfall was to be made up by deferring purchases, restricting travel, and a hiring freeze. The deficit resulted from reduced tax collections.

UFW, Teamsters again settle jurisdictional dispute

Renewal of jurisdictional disputes between the United Farm Workers and the Teamsters over organizing agricultural workers in California and other Western States was averted when a peace treaty, scheduled to expire in March, was extended for 1 year. The original 5-year treaty, signed in 1977, ended a struggle between the unions that began about 10 years earlier. (See *Monthly Labor Review*, May 1977, pp. 57–58). Under the agreement, the Farm Workers organize workers engaged in growing agricultural products and the Teamsters organize workers engaged in processing, preserving, and transporting farm products.

Prior to announcement of the agreement extension, Farm Workers' President Cesar Chavez had blamed the Teamsters for his union's financial and operating difficulties. A Teamsters' official said that if his union stayed out of farm labor, "it will give the lie to those who say we Teamsters are to blame for the weakening or the end of the UFW."

State employees get raise, minus 2 weeks of pay

About 165,000 employees of New York State were covered by 3-year agreements that provided similar overall gains in wages and benefits. All of the contracts provided for adoption of delays in paydays that were expected to save the State $88 million this fiscal year.

One of the settlements involved 107,000 administrative, clerical, and blue-collar employees represented by the Civil Service Employees Association. It provided for a 9-percent pay increase on April 1, 1982, and for 5 percent increases on April 1 and September 1 of 1983 and 1984. These employees previously averaged $11,395 a year. To help minimize the immediate cost of this accord, which also called for benefit improvements, the union agreed to a 2-week lag in payrolls. Under this procedure, paychecks will be delayed 1 additional day in each biweekly pay period, resulting in a cumulative delay of 10 workdays. At retirement, workers will be paid for the 10 days at the pay rates they are then receiving.

In a change sought by the union, the parties agreed to end a performance evaluation system which tied workers' pay to managements' assessment of their work. Instead, the parties agreed to return to the prior system, under which all workers in a particular grade will receive the same increase, if their individual performance is at least satisfactory.

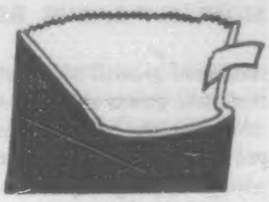
The second settlement, covering 47,000 professional, scientific, and technical workers, provided for a 9-percent salary increase effective April 1, 1982, and for 8 percent increases on each of the next two anniversaries. This settlement, negotiated by the Public Employees Federation, also provided that workers hired after March 31, 1982, accrue 10 days of sick leave and 3 days of personal leave a year, while those already on the payroll will continue to accrue 13 days of sick leave and 5 days of personal leave.

The final settlement, with Council 82 of the State, County and Municipal Employees, provided for essentially the same provisions as those won by the Civil Service Employees Association. One difference was that the witholding of 2 weeks of pay will be accomplished by paying employees for 9½ days (instead of 10 days) for 20 consecutive pay periods.

Ship pilots get pay increase

The 39 pilots who maneuver ships on the lower Columbia River will earn about $90,000 a year (an 11-percent increase) as a result of a decision by the Oregon Board of Maritime Pilots. The pilots earnings now are calculated at 6.2 cents per registered ton and $9.35 per draft foot, rising by 10 percent each in February 1983. In addition, they will receive a surcharge of $100 for each 50 feet of ship length above 699 feet. The pilots handled an average of 133 ships in 1980. Similar increases were being considered for other ship pilots in the area. □

Book Reviews



Social policies for the aging

The Elderly and the Future Economy. By Lawrence Olsen, Christopher Caton, and Martin Duffy, with contributions by Michael Shannon and Robert Tannenwald. Lexington, Mass., D. C. Heath and Co., Lexington Books, 1981. 143 pp., bibliography. $19.95.

This book was prepared by Lawrence Olsen, Christopher Caton, and Martin Duffy, all members of the staff of Data Resources, Inc. (DRI), to supplement the work of the Technical Committee on the Economy of the recent 1981 White House Conference on Aging. Using forecasting techniques based on two simulation models, the authors attempt to assess the general macroeconomic outlook for the period 1980 through 2005, how various age groups in the population will fare during this time period, and the effect on both the income position and status of both elderly and nonelderly individuals and families if four policy options, or a mix thereof, were to be enacted and put into operation over the next 25 years or so.

The four policy options selected for analysis were (1) increased labor force participation of "elderly" workers (age 65 and over) and "nonelderly" workers (age 55–64); (2) a national income guarantee program for the elderly; (3) an increase in personal saving rates by the nonelderly beginning in 1981, and (4) "investment-oriented" corporate tax cuts, also beginning in 1981. No detailed rationale is provided for the selection of these options, only one of which is an income transfer proposal.

After introductory and review of the literature chapters, chapter 3 outlines the DRI baseline simulation model of the economy through 2005. It forecasts slower rates of increase for both the GNP and consumption growth than experienced over the past two decades, only a slow moderation of inflation, and a slowing of the real-income growth of the elderly, at least when compared to the past decade or so. While the real income of the elderly as a group is projected to show some gains, the baseline model forecasts that significant numbers of the elderly population will have low incomes well into the 21st century. A welcome highlight of chapter 3 is the explanation and discussion of the two models, the DRI Macroeconomic Model and the DRI Demographic-Economic Model of the Elderly. The latter was used to project trends in elderly and nonelderly income by various age groups (under age 55, 55–61, 62–64, 65–71, and 72 and over), by family status and income level. The authors are to be commended for the complete income distribution tables for each of these age groups, discussed in both the text and the appendices material.

The next four chapters cover the aforementioned policy options and their macroeconomic effects as well as their effects on income and its distribution between nonelderly and elderly individuals and families. Chapter 4 assesses the effect of increased labor force participation by older people, and both the macroeconomic and income status of the elderly show some general improvement under this option, although the very oldest and the poorest benefit little. Chapter 5 examines the effects of guaranteeing the elderly an adequate level of income beginning in 1981. Interestingly, the minimum standard for income adequacy was the Bureau of Labor Statistics' "Intermediate Budget Level for a Retired Couple in 1979 ($8,562)," and indexed annually thereafter. While the initial annual cost of such an income guarantee is high, some $18 billion the first year, it would have only minimal effects on the economy as a whole, and, of course, prove to be a highly effective mechanism for assuring income adequacy to elderly families and individuals in greatest economic need.

Chapters 6 and 7 discuss options that, in some ways, have either already been implemented or are among the objectives of the Reagan Administration. Chapter 6 analyzes the effects of a personal saving-rate increase by nonelderly workers of about 2-percent higher than the saving rate variable built into the DRI Macroeconomic Model. The personal savings option would lead, according to DRI's analyses, to an appreciable growth of the real gross national product, especially from the period 1986 on. However, gains for the elderly are projected as being slow under this option; not until the year 2000 would the average real income of the elderly population rise above its baseline amount. In chapter 7, investment-oriented corporate tax cuts are analyzed. While economic growth substantially increases under this option, DRI points out that in the absence of new transfer initiatives, the elderly benefit less from the economic improvements that would result from this option than younger age groups. And, DRI emphasizes that this would be especially true for the poorest and the oldest among the older population.

The final chapter compares the various options with each other and with the baseline macroeconomic model. The authors argue for some mix of the various options discussed, although they point out that the greatest gains for the elderly would take place under either an increase in the labor force participation rates of the elderly and near elderly and, of course, the income guarantee option pegged to the BLS Intermediate Budget Level. It is a carefully written and analytical discussion that should aid policymakers at the national level, and those attempting to influence them, with a more sophisticated understanding of these options, their specific policy implications, and their effect on the economy as a whole.

Appendix A should also be mentioned. It includes the various assumptions used in the development of DRI's Macroeconomic simulation, including assumptions in such areas as labor force growth, employment and unemployment growth and rates, energy and energy policy, fiscal policy, consumption expenditures, housing, business investment, State and local spending, and productivity.

If one can assume that there is a fair degree of reliability in the basic DRI Macroeconomic Models and their Demographic-Economic Model, then this book may break some new ground insofar as social policy in the broad field of aging is concerned. The book should be particularly attractive to those working in the field of public retirement income programs, as legislators or policy analysts, including those analysts now working in various organizations attempting to influence national retirement income policy.

Another look at labor market theory

Labor Economics: The Emerging Synthesis. By Robert M. Fearn. Cambridge, Mass., Winthrop Publishers, 1981. 278 pp. $14.50.

Robert Fearn, it appears, is determined to make economic labor market theory come alive. This book is among the new order of "analytical" labor economics texts emphasizing the applicability of neoclassical economic theory and techniques in the analysis of contemporary labor market issues. Where other authors have failed, Fearn succeeds in (1) identifying the most pressing of today's labor problems and (2) presenting a cogent review of the most important literature bearing on the issues. Indeed, it is in the literature review of each issue that Fearn's book is generally at its best. Early in the work, however, it becomes clear that Fearn disregards his arsenal of knowledge and technique and becomes distracted on mundane side issues.

Fearn covers issues ranging from the economics of women's liberation to the traditional chapter on the distribution of income. His introduction includes an excellent discussion of the changing nature and emphasis of labor economic study. It is here that the topical approach is explained and justified. A telling omission, however, is any indication of the theoretical and quantitative sophistication assumed of the book's readers. This omission returns to haunt the work in many chapters, for it becomes apparent that Fearn's vacillation on the level of analysis stems from either uncertainty regarding the nature of his audience or a futile attempt to serve the purposes of all.

There are several excellent chapters in the book, representing Fearn's ability to identify a meaningful problem and synthesize available literature on the subject. Chapter 8, "The Demand for Human Capital," is a subject traditionally covered in most labor texts. Fearn's contribution to the issue is most enlightening in his presentation of " . . . practical lessons for career choosers, guidance counselors, and others." "The Economics of Unions" chapter is superb as a review of the recent literature. Unfortunately, the treatment of unionism as a consumer good, a monopoly influence, and a cheap screening device, suffers from unnecessary attempts to blend mathematical rigor into the analysis. The discussion of unionism is highlighted, nonetheless, by an empirical investigation of the determinants of union membership and union wage effects. An exceptional chapter, "Economics of Women's Liberation," presents a lucid explanation of female labor force participation influences and skillfully separates the economic from noneconomic forces.

Fearn's book makes a substantial contribution to the labor economics literature, particularly in presenting concepts, theories, and literature reviews in an interesting topical framework. This achievement is marred, however, by extended presentations of mathematical model specifications. If the author considers such elaborations to be necessary, they would more appropriately be presented as chapter appendices.

As many authors are prone to do, Fearn occasionally gets carried away with digressions that detract from the major components of this analysis. Such is the case in the first chapter, "Labor Markets and Labor Force Attachment," where the discussion of "communards" and communal living is stretched over 13 pages in the following sections: "Indifference Curve Analysis and Communal Distribution; A Small Commune, or Tea for Two; Communes and 'Copping' or 'Opting Out'; and Communes, Households and Labor Force Attachment." A similar redundancy shows up in the presentation of President Nixon's Family Assistance Plan (FAP) in the chapter on "Welfare Programs and Work Incentives." While Fearn presents a straightforward treatment of many of the major issues surrounding income maintenance programs, in place of his diversion to mathematical elucidation of the FAP model could have been a simple algebraic formulation demonstrating that the principal objectives of U.S. welfare policy are mutually inconsistent.

Labor Economics: An Emerging Synthesis should be read by students of labor economics (and teachers) interested in an up-to-date analysis of current labor problems. While I argue at some points with Fearn's presentation, I find the book generally to be free of major errors of analysis and interpretation.

Foreign policy: ways and means

Solvency—The Price of Survival: An Essay on American Foreign Policy. By James Chace. New York, Random House, Inc., 1981. 115 pp. $9.95.

In a clear, accessible, even personable style, James Chace, the managing editor of *Foreign Affairs,* addresses the conduct of foreign relations and economic policy with broad, vigorous strokes. At the same time, he illuminates the subtle and generally unexamined interstices between these two fields with a clarity not too short of brilliance. After reading this book, we can understand that a $1.5 trillion unfunded liability in the Social Security system may keep a strategic window of vulnerability open that much wider or that today's high rate of unemployment could mean that a U.S. Army division will have to go 1 more year without updating its equipment. These are some of the hard choices that must be made when competing commitments meet the reality of too scarce resources.

Tension between wants and means is the foundation of Chace's discussion of foreign policy. His analysis can be reduced, with admitted oversimplification, to a variety of accounting problems. On the debit side are the national security commitments, the international political debts, the promises made to others in conducting foreign policy, and the huge domestic commitments America has made to its own people. On the credit side, there are the promises and commitments returned to the United States, the Nation's standing military power, and the fecundity of the economy. In such an accounting framework, Chace quotes Walter Lippmann:

> . . . the level may vary at which a solvent balance is struck. If its expenditures are safely within its assured means, a family is solvent if it is poor, is well-to-do, or is rich. The same principle holds true of nations. The statesman of a strong country may balance its commitments at a high level or at a low. But whether he is conducting the affairs of Germany, which has had dynamic ambitions, or the affairs of Switzerland, which seeks to hold what it already has, or the United States, he must bring his means and ends into balance. If he does not, he will follow a course that leads to disaster.

James Chace argues that we are well along such a course. We have spent too much—Chace is especially mindful of Vietnam—and we are building too little.

The analysis of the economy and why it is not producing enough is less assured than Chace's commentary on foreign affairs. His economics rely heavily on the oldtime religion that holds its meetings in the middle of the road that runs past the Wall in lower Manhattan: The government has spent too much and taxed too little; the authorities have printed too much money to make up the difference; and we have all gotten too lazy and complacent in our labor. The theory is arguable, but the implications are clear—the United States is no longer so overwhelmingly dominant an economy that it can more or less demand, and generally get, its own political and economic terms on all issues. The United States must now choose between its "vital interests" and "secondary goals" and, in many ways, must learn to define these concepts in terms of the limited means available.

Solvency is a provocative and disturbing book. Words like "retrenchment" and "withdrawal" and even "isolation" can whisper through one's thoughts. Simple logical extension of Chace's theme of bringing means and ends into balance leads to thoughts of digging into a new, nuclear Fortress America. But I think Chace would agree that policy can be made to cope with the solvency crisis without drawing back from our basic commitment as the principal country among the free nations of the world. I would like to add that the parameters of that exercise may not ultimately be set in Washington's foreign policy councils, but on the boardroom tables and shop floors of America's production machine.

35. Wage and compensation change, major collective bargaining settlements, 1977 to date 102
36. Effective wage adjustments in collective bargaining units covering 1,000 workers or more, 1977 to date 102

Work stoppage data. Definition 103
37. Work stoppages involving 1,000 workers or more, 1947 to date 103

NOTES ON CURRENT LABOR STATISTICS

This section of the *Review* presents the principal statistical series collected and calculated by the Bureau of Labor Statistics. A brief introduction to each group of tables provides definitions, notes on the data, sources, and other material usually found in footnotes.

Readers who need additional information are invited to consult the BLS regional offices listed on the inside front cover of this issue of the *Review*. Some general notes applicable to several series are given below.

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might otherwise mask short-term movements of the statistical series. Tables containing these data are identified as "seasonally adjusted." Seasonal effects are estimated on the basis of past experience. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years.

Seasonally adjusted labor force data in tables 2–7 were revised in the March 1982 issue of the *Review* to reflect experience through 1981. The original estimates also were revised to 1970 to reflect 1980 census population controls.

Beginning in January 1980, the BLS introduced two major modifications in the seasonal adjustment methodology for labor force data. First, the data are being seasonally adjusted with a new procedure called X-11/ARIMA, which was developed at Statistics Canada as an extension of the standard X-11 method. A detailed description of the procedure appears in *The X-11 ARIMA Seasonal Adjustment Method* by Estela Bee Dagum (Statistics Canada Catalogue No. 12-564E, February 1980). The second change is that seasonal factors are now being calculated for use during the first 6 months of the year, rather than for the entire year, and then are calculated at mid-year for the July-December period. Revisions of historical data continue to be made only at the end of each calendar year.

Annual revision of the seasonally adjusted payroll data in tables 11, 14, and 16 begins with the August 1980 issue using the X-11 ARIMA seasonal adjustment methodology. New seasonal factors for productivity data in tables 30 and 31 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month to month and from quarter to quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average All Items CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100. For example, given a current hourly wage rate of $3 and a current price index number of 150, where 1967 = 100, the hourly rate expressed in 1967 dollars is $2 ($3/150 × 100 = $2). The resulting values are described as "real," "constant," or "1967" dollars.

Availability of information. Data that supplement the tables in this section are published by the Bureau of Labor Statistics in a variety of sources. Press releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule given below. The *BLS Handbook of Labor Statistics*, Bulletin 2070, provides more detailed data and greater historical coverage for most of the statistical series presented in the *Monthly Labor Review*. More information from the household and establishment surveys is provided in *Employment and Earnings*, a monthly publication of the Bureau. Historically, comparable information from the establishment survey is published in two comprehensive data books—*Employment and Earnings, United States* and *Employment and Earnings, States and Areas*, and their annual supplements. More detailed information on wages and other aspects of collective bargaining appears in the monthly periodical, *Current Wage Developments*. More detailed price information is published each month in the periodicals, the *CPI Detailed Report* and *Producer Prices and Price Indexes*.

Symbols

p = preliminary. To improve the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.
r = revised. Generally, this revision reflects the availability of later data but may also reflect other adjustments.
n.e.c. = not elsewhere classified.

Schedule of release dates for major BLS statistical series

Series	Release date	Period covered	Release date	Period covered	MLR table number
Employment situation	July 2	June	August 6	July	1–11
Producer Price Index	July 16	June	August 13	July	23–27
Consumer Price Index	July 23	June	August 24	July	19–22
Real earnings	July 23	June	August 21	July	12–17
Productivity and costs:					
Nonfarm business and manufacturing	July 29	2nd quarter	....	....	28–31
Nonfinancial corporations	....	....	August 26	2nd quarter	28–31
Employment Cost Index	....	....	August 19	2nd quarter	32–34

EMPLOYMENT DATA FROM THE HOUSEHOLD SURVEY

EMPLOYMENT DATA in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 60,000 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

Definitions

Employed persons are (1) those who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work because they were on layoff or waiting to start new jobs within the next 30 days are also counted among the unemployed. The **unemployment rate** represents the number unemployed as a percent of the civilian labor force.

The **civilian labor force** consists of all employed or unemployed persons in the civilian noninstitutional population; the **total labor force** includes military personnel. Persons **not in the labor force** are those not classified as employed or unemployed; this group includes persons retired, those engaged in their own housework, those not working while attending school, those unable to work because of long-term illness, those discouraged from seeking work because of personal or job market factors, and those who are voluntarily idle. The **noninstitutional population** comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy.

Full-time workers are those employed at least 35 hours a week; **part-time workers** are those who work fewer hours. Workers on part-time schedules for economic reasons (such as slack work, terminating or starting a job during the week, material shortages, or inability to find full-time work) are among those counted as being on full-time status, under the assumption that they would be working full time if conditions permitted. The survey classifies unemployed persons in full-time or part-time status by their reported preferences for full-time or part-time work.

Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the preceding years. These adjustments affect the comparability of historical data presented in table 1. A description of these adjustments and their effect on the various data series appear in the Explanatory Notes of *Employment and Earnings*.

Data in tables 2–7 are seasonally adjusted, based on the seasonal experience through December 1981.

1. Employment status of the noninstitutional population, 16 years and over, selected years, 1950–81

[Numbers in thousands]

Year	Total noninstitutional population	Total labor force		Civilian labor force						Not in labor force
		Number	Percent of population	Total	Employed			Unemployed		
					Total	Agriculture	Nonagricultural industries	Number	Percent of labor force

EMPLOYMENT, HOURS, AND EARNINGS DATA FROM ESTABLISHMENT SURVEYS

EMPLOYMENT, HOURS, AND EARNINGS DATA in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by 177,000 establishments representing all industries except agriculture. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

Definitions

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12th of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in manufacturing include blue-collar worker supervisors and all nonsupervisory workers closely associated with production operations. Those workers mentioned in tables 12–17 include production workers in manufacturing and mining; construction workers in construction; and nonsupervisory workers in transportation and public utilities; in wholesale and retail trade; in finance, insurance, and real estate; and in services industries. These groups account for about four-fifths of the total employment on private nonagricultural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. **Real earnings** are earnings adjusted to eliminate the effects of price change, using the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W). The **Hourly Earnings Index** is calculated from average hourly earnings data adjusted to exclude the effects of two types of changes that are unrelated to underlying wage-rate developments: fluctuations in overtime premiums in manufacturing (the only sector for which overtime data are available) and the effects of changes and seasonal factors in the proportion of workers in high-wage and low-wage industries.

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received and are different from standard or scheduled hours. **Overtime hours** represent the portion of gross average weekly hours which were in excess of regular hours and for which overtime premiums were paid.

Notes on the data

Establishment data collected by the Bureau of Labor Statistics are periodically adjusted to comprehensive counts of employment (called "benchmarks"). The latest complete adjustment was made with the release of May 1982 data, published in the July 1982 issue of the *Review*. Consequently, data published in the *Review* prior to that issue are not necessarily comparable to current data. Complete comparable historical unadjusted and seasonally adjusted data are published in a Supplement to Employment and Earnings (unadjusted data from April 1977 through February 1982 and seasonally adjusted data from January 1974 through February 1982) and in *Employment and Earnings, United States, 1909–78*, BLS Bulletin 1312–11 (for prior periods).

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20. See also *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976).

NOTE: The industry divisions of mining; construction; tobacco manufactures (a major manufacturing group, nondurable goods); transportation and public utilities; and finance, insurance, and real estate are no longer shown. This is because the seasonal component in these is small relative to the trend-cycle, or irregular components, or both, and consequently cannot be precisely separated.

NOTE: In accordance with usual practice, BLS has revised establishment survey data to reflect a new benchmark and updated seasonal adjustment factors. Because of these revisions, establishment data in this table may differ from data published earlier. See technical note, page 70.

15. Hourly earnings, by industry division and major manufacturing group

[1] Over-the-year percent change before seasonal adjustment.

[2] This series is not seasonally adjusted because the seasonal component is small relative to the trend-cycle, irregular components, or both, and consequently cannot be separated with sufficient precision.

[3] Not available.

NOTE: In accordance with usual practice, BLS has revised establishment survey data to reflect a new benchmark and updated seasonal adjustment factors. Because of these revisions, establishment data in this table may differ from data published earlier. See technical note, page 70.

17. Weekly earnings, by industry division and major manufacturing group

UNEMPLOYMENT INSURANCE DATA

NATIONAL UNEMPLOYMENT INSURANCE DATA are compiled monthly by the Employment and Training Administration of the U.S. Department of Labor from monthly reports of unemployment insurance activity prepared by State agencies. Railroad unemployment insurance data are prepared by the U.S. Railroad Retirement Board.

Definitions

Data for **all programs** represent an unduplicated count of insured unemployment under State programs, Unemployment Compensation for Ex-Servicemen, and Unemployment Compensation for Federal Employees, and the Railroad Insurance Act.

Under both State and Federal unemployment insurance programs for civilian employees, insured workers must report the completion of at least 1 week of unemployment before they are defined as unemployed. Persons not covered by unemployment insurance (about 10 percent of the labor force) and those who have exhausted or not yet earned benefit rights are excluded from the scope of the survey. **Initial claims** are notices filed by persons in unemployment insurance programs to indicate they are out of work and wish to begin receiving compensation. A claimant who continued to be unemployed a full week is then counted in the insured unemployment figure. The **rate of insured unemployment** expresses the number of insured unemployed as a percent of the average insured employment in a 12-month period.

An **application** for benefits is filed by a railroad worker at the beginning of his first period of unemployment in a benefit year; no application is required for subsequent periods in the same year. **Number of payments** are payments made in 14-day registration periods. The **average amount of benefit payment** is an average for all compensable periods, not adjusted for recovery of overpayments or settlement of underpayments. However, **total benefits paid** have been adjusted.

18. Unemployment insurance and employment service operations

[All items except average benefits amounts are in thousands]

Item	1981									1982

[1] Initial claims and State insured unemployment include data under the program for Puerto Rican sugarcane workers.

[2] Includes interstate claims for the Virgin Islands. Excludes transition claims under State programs.

[3] Excludes data on claims and payments made jointly with other programs.

[4] Excludes data on claims and payments made jointly with State programs.

[5] Cumulative total for fiscal year (October 1-September 30). Data computed quarterly.

NOTE: Data for Puerto Rico and the Virgin Islands included. Dashes indicate data not available.

r = revised.

PRICE DATA

PRICE DATA are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base period (1967 = 100, unless otherwise noted).

Definitions

The **Consumer Price Index** is a monthly statistical measure of the average change in prices in a fixed market basket of goods and services. Effective with the January 1978 index, the Bureau of Labor Statistics began publishing CPI's for two groups of the population. One index, a new CPI for All Urban Consumers, covers 80 percent of the total noninstitutional population; and the other index, a revised CPI for Urban Wage Earners and Clerical Workers, covers about half the new index population. The All Urban Consumers index includes, in addition to wage earners and clerical workers, professional, managerial, and technical workers, the self-employed, short-term workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctor's and dentist's fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items is kept essentially unchanged between major revisions so that only price changes will be measured. Prices are collected from over 18,000 tenants, 24,000 retail establishments, and 18,000 housing units for property taxes in 85 urban areas across the country. All taxes directly associated with the purchase and use of items are included in the index. Because the CPI's are based on the expenditures of two population groups in 1972–73, they may not accurately reflect the experience of individual families and single persons with different buying habits.

Though the CPI is often called the "Cost-of-Living Index," it measures only price change, which is just one of several important factors affecting living costs. Area indexes do not measure differences in the level of prices among cities. They only measure the average change in prices for each area since the base period.

Producer Price Indexes measure average changes in prices received in primary markets of the United States by producers of commodities in all stages of processing. The sample used for calculating these indexes contains about 2,800 commodities and about 10,000 quotations per month selected to represent the movement of prices of all commodities produced in the manufacturing, agriculture, forestry, fishing, mining, gas and electricity, and public utilities sectors. The universe includes all commodities produced or imported for sale in commercial transactions in primary markets in the United States.

Producer Price Indexes can be organized by stage of processing or by commodity. The stage of processing structure organizes products by degree of fabrication (that is, finished goods, intermediate or semifinished goods, and crude materials). The commodity structure organizes products by similarity of end-use or material composition.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States, from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

In calculating Producer Price Indexes, price changes for the various commodities are averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1972. The detailed data are aggregated to obtain indexes for stage of processing groupings, commodity groupings, durability of product groupings, and a number of special composite groupings.

Price indexes for the output of selected SIC industries measure average price changes in commodities produced by particular industries, as defined in the *Standard Industrial Classification Manual 1972* (Washington, U.S. Office of Management and Budget, 1972). These indexes are derived from several price series, combined to match the economic activity of the specified industry and weighted by the value of shipments in the industry. They use data from comprehensive industrial censuses conducted by the U.S. Bureau of the Census and the U.S. Department of Agriculture.

Notes on the data

Beginning with the May 1978 issue of the *Review*, regional CPI's cross classified by population size, were introduced. These indexes will enable users in local areas for which an index is not published to get a better approximation of the CPI for their area by using the appropriate population size class measure for their region. The cross-classified indexes will be published bimonthly. (See table 21.)

For further details about the new and the revised indexes and a comparison of various aspects of these indexes with the old unrevised CPI, see *Facts About the Revised Consumer Price Index*, a pamphlet in the Consumer Price Index Revision 1978 series. See also *The Consumer Price Index: Concepts and Content Over the Years*, Report 517, revised edition (Bureau of Labor Statistics, May 1978).

For interarea comparisons of living costs at three hypothetical standards of living, see the family budget data published in the *Handbook of Labor Statistics, 1977*, Bulletin 1966 (Bureau of Labor Statistics, 1977), tables 122–133. Additional data and analysis on price changes are provided in the *CPI Detailed Report* and *Producer Prices and Price Indexes*, both monthly publications of the Bureau.

As of January 1976, the Wholesale Price Index (as it was then called) incorporated a revised weighting structure reflecting 1972 values of shipments. From January 1967 through December 1975, 1963 values of shipments were used as weights.

For a discussion of the general method of computing consumer, producer, and industry price indexes, see *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976), chapters 13–15. See also John F. Early, "Improving the measurement of producer price change," *Monthly Labor Review*, April 1978, pp. 7–15. For industry prices, see also Bennett R. Moss, "Industry and Sector Price Indexes," *Monthly Labor Review*, August 1965, pp. 974–82.

[1] Data for January 1982 have been revised to reflect the availability of late reports and corrections by respondents. All data are subject to revision 4 months after original publication.

[2] Prices for natural gas are lagged 1 month.

[3] Includes only domestic production.

[4] Most prices for refined petroleum products are lagged 1 month.

[5] Some prices for industrial chemicals are lagged 1 month.

[6] Not available.

r = revised.

25. Producer Price Indexes, for special commodity groupings

[1967=100 unless otherwise specified]

Commodity grouping	Annual average 1981	1981 May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	1982 Jan.[1]	Feb.	Mar.	Apr.	May
All commodities — less farm products	295.7	296.1	296.7	298.0	298.7	298.5	299.5	299.4	300.0	r302.0	301.8	301.4	300.9	301.1
All foods	251.9	250.3	252.2	255.2	253.7	251.7	249.1	247.4	247.6	r251.3	253.5	251.5	254.4	257.9

r = revised.

PRODUCTIVITY DATA

PRODUCTIVITY DATA are compiled by the Bureau of Labor Statistics from establishment data and from estimates of compensation and output supplied by the U.S. Department of Commerce and the Federal Reserve Board.

Definitions

Output is the constant dollar gross domestic product produced in a given period. Indexes of **output per hour of labor input,** or labor productivity, measure the value of goods and services produced per hour of labor. **Compensation per hour** includes wages and salaries of employees plus employers' contributions for social insurance and private benefit plans. The data also include an estimate of wages, salaries, and supplementary payments for the self-employed, except for nonfinancial corporations, in which there are no self-employed. **Real compensation per hour** is compensation per hour adjusted by the Consumer Price Index for All Urban Consumers.

Unit labor cost measures the labor compensation cost required to produce one unit of output and is derived by dividing compensation by output. **Unit nonlabor payments** include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from the current dollar gross domestic product and dividing by output. In these tables, **unit nonlabor costs** contain all the components of unit nonlabor payments except unit profits. **Unit profits** include corporate profits and inventory valuation adjustments per unit of output.

The **implicit price deflator** is derived by dividing the current dollar estimate of gross product by the constant dollar estimate, making the deflator, in effect, a price index for gross product of the sector reported.

The use of the term "man hours" to identify the labor component of productivity and costs, in tables 28 through 31, has been discontinued. **Hours of all persons** is now used to describe the labor input of payroll workers, self-employed persons, and unpaid family workers. **Output per all-employee hour** is now used to describe labor productivity in nonfinancial corporations where there are no self-employed.

Notes on the data

In the private business sector and the nonfarm business sector, the basis for the output measure employed in the computation of output per hour is Gross Domestic Product rather than Gross National Product. Computation of hours includes estimates of nonfarm and farm proprietor hours.

Output data are supplied by the Bureau of Economic Analysis, U.S. Department of Commerce, and the Federal Reserve Board. Quarterly manufacturing output indexes are adjusted by the Bureau of Labor Statistics to annual estimates of output (gross product originating) from the Bureau of Economic Analysis. Compensation and hours data are from the Bureau of Economic Analysis and the Bureau of Labor Statistics.

Beginning with the September 1976 issue of the *Review*, the productivity tables were revised to reflect changeover to the new series—private business sector and nonfarm business sector—which differ from the previously published total private economy and nonfarm sector in that output imputed for owner-occupied dwellings and the household and institutions sectors, as well as the statistical discrepancy, are omitted. For a detailed explanation, see J. R. Norsworthy and L. J. Fulco, "New sector definitions for productivity series," *Monthly Labor Review*, October 1976, pages 40–42.

28. Annual indexes of productivity, hourly compensation, unit costs, and prices, selected years, 1950–81

WAGE AND COMPENSATION DATA

Data for the Employment Cost Index are reported to the Bureau of Labor Statistics by a sample of 2,000 private nonfarm establishments and 750 State and local government units selected to represent total employment in those sectors. On average, each reporting unit provides wage and compensation information on five well-specified occupations.

Data on negotiated wage and benefit changes are obtained from contracts on file at the Bureau, direct contact with the parties, and secondary sources.

Definitions

The **Employment Cost Index** (ECI) is a quarterly measure of the average change in the cost of employing labor. The rate of total compensation, which comprises wages, salaries, and employer costs for employee benefits, is collected for workers performing specified tasks. Employment in each occupation is held constant over time for all series produced in the ECI, except those by region, bargaining status, and area. As a consequence, only changes in compensation are measured. Industry and occupational employment data from the 1970 Census of Population are used in deriving constant weights for the ECI. While holding total industry and occupational employment fixed, in the estimation of indexes by region, bargaining status, and area, the employment in those measures is allowed to vary over time in accord with changes in the sample. The rate of change (in percent) is available for wages and salaries, as well as for total compensation. Data are collected for the pay period including the 12th day of the survey months of March, June, September, and December. The statistics are neither annualized nor adjusted for seasonal influence.

Wages and salaries consist of earnings before payroll deductions, excluding premium pay for overtime, work on weekends and holidays, and shift differentials. Production bonuses, incentive earnings, commissions, and cost-of-living adjustments are included; nonproduction bonuses are included with other supplemental pay items in the benefits category; and payments-in-kind, free room and board, and tips are excluded. *Benefits* include supplemental pay, insurance, retirement and savings plans, and hours-related and legally required benefits.

Data on negotiated wage changes apply to private nonfarm industry collective bargaining agreements covering 1,000 workers or more. Data on compensation changes apply only to those agreements covering 5,000 workers or more. *First-year* wage or compensation changes refer to average negotiated changes for workers covered by settlements reached in the period and implemented within the first 12 months after the effective date of the agreement. *Changes over the life of the agreement* refer to all adjustments specified in the contract, expressed as an average annual rate. These measures exclude wage changes that may occur under cost-of-living adjustment clauses, that are triggered by movements in the Consumer Price Index. *Wage-rate changes* are expressed as a percent of straight-time hourly earnings; *compensation changes* are expressed as a percent of total wages and benefits.

Effective wage adjustments reflect all negotiated changes implemented in the reference period, regardless of the settlement date. They include changes from settlements reached during the period, changes deferred from contracts negotiated in an earlier period, and cost-of-living adjustments. The data also reflect contracts providing for no wage adjustment in the period. Effective adjustments and each of their components are prorated over all workers in bargaining units with at least 1,000 workers.

Notes on the data

The Employment Cost Index data series began in the fourth quarter of 1975, with the quarterly percent change in wages and salaries in the private nonfarm sector. Data on employer costs for employee benefits were included in 1980, to produce a measure of the percent change in employers' cost for employees' total compensation. State and local government units were added to the ECI coverage in 1981, providing a measure of total compensation change in the civilian nonfarm economy.

Data for the broad white-collar, blue-collar, and service worker groups, and the manufacturing, nonmanufacturing, and service industry groups are presented at the ECI. Additional occupation and industry detail are provided for the wages and salaries component of total compensation in the private nonfarm sector. For State and local government units, additional industry detail is shown for both total compensation and its wages and salaries component.

Historical indexes (June 1981 = 100) of the quarterly rates of changes presented in the ECI are also available.

For a more detailed discussion of the ECI, see chapter 25, "The Employment Cost Index," of the BLS *Handbook of Methods* (Bulletin 1910), and the *Monthly Labor Review* articles: "Employment Cost Index: a measure of change in the 'price of labor,'" July 1975; "How benefits will be incorporated into the Employment Cost Index," January 1978; and "The Employment Cost Index: recent trends and expansion," May 1982.

Additional data for the ECI and other measures of wage and compensation changes appear in *Current Wage Developments*, a monthly periodical of the Bureau.

Wage rate changes covering at least 1,000 workers, all industries:													
First year of contract	7.6	7.4	9.5	9.8	8.2	9.1	10.5	8.3	7.1	11.8	10.8	9.0	2.2
Annual rate over life of contract	6.4	6.0	7.1	7.9	6.5	7.3	7.4	6.5	6.2	8.7	8.7	5.7	2.0
Manufacturing:													
First year of contract	8.3	6.9	7.4	7.2	7.2	6.7	8.4	7.8	6.4	8.2	9.0	6.6	1.9
Annual rate over life of contract	6.6	5.4	5.4	6.1	5.7	5.1	5.6	5.8	5.5	6.7	7.5	5.4	1.8
Nonmanufacturing (excluding construction):													
First year of contract	8.0	7.6	9.5	9.8	9.6	10.3	9.5	9.2	8.0	11.8	8.6	9.6	1.8
Annual rate over life of contract	6.5	6.2	6.6	7.3	7.6	8.5	5.9	6.6	7.3	9.1	7.2	5.6	1.4
Construction:													
First year of contract	6.5	8.8	13.6	13.5	10.8	12.2	15.4	14.3	11.4	12.9	16.4	11.4	9.3
Annual rate over life of contract	6.2	8.3	11.5	11.3	9.1	10.4	13.0	12.0	10.3	11.1	12.4	11.7	8.9

36. Effective wage adjustments in collective bargaining units covering 1,000 workers or more, 1977 to date

Measure	Year					Year and quarter								
						1980				1981				1982^p
	1977	1978	1979	1980	1981	I	II	III	IV	I	II	III	IV	I
Average percent adjustment (including no change):														
All industries	8.0	8.2	9.1	9.9	9.5	1.6	3.3	3.5	1.3	1.7	3.2	3.3	1.5	.9
Manufacturing	8.4	8.6	9.8	10.2	9.4	2.0	3.4	2.9	1.7	2.3	2.4	3.1	1.9	.8
Nonmanufacturing	7.6	7.9	8.8	9.7	9.5	1.3	3.2	4.0	1.1	1.2	3.8	3.4	1.1	1.0
From settlements reached in period	3.0	2.0	3.0	3.6	2.5	.4	1.0	1.7	.5	.4	1.1	.5	.4	.1
Deferred from settlements reached in earlier period	3.2	3.7	3.0	3.5	3.8	.5	1.4	1.2	.3	.5	1.4	1.5	.4	.5
From cost-of-living clauses	1.7	2.4	3.1	2.8	3.2	.7	.8	.7	.6	.7	.7	1.2	.6	.2
Total number of workers receiving wage change (in thousands)[1]	—	—	—	—	8,648	—	—	—	—	3,856	4,701	4,364	3,225	2,713
From settlements reached in period	—	—	—	—	2,270	—	—	—	—	579	906	540	604	158
Deferred from settlements reached in earlier period	—	—	—	—	6,207	—	—	—	—	888	2,056	3,023	882	1,033
From cost-of-living clauses	—	—	—	—	4,503	—	—	—	—	2,636	2,889	2,934	2,179	1,750
Number of workers receiving no adjustments (in thousands)	—	—	—	—	145	—	—	—	—	4,937	4,062	4,428	5,566	[illegible]

[1] The total number of workers who received adjustments does not equal the sum of workers that received each type of adjustment, because some workers received more than one type of adjustment during the period.

WORK STOPPAGE DATA

Work stoppages include all known strikes or lockouts involving 1,000 workers or more and lasting a full shift or longer. Data are based largely on newspaper accounts and cover all workers idle one shift or more in establishments directly involved in a stoppage. They do not measure the indirect or secondary effect on other establishments whose employees are idle owing to material or service shortages.

Estimates of days idle as a percent of estimated working time measures only the impact of larger strikes (1,000 workers or more). Formerly, these estimates measured the impact of strikes involving 6 workers or more; that is, the impact of virtually *all* strikes. Due to budget stringencies, collection of data on strikes involving 6 workers or more was discontinued with the December 1981 data.

37. Work stoppages involving 1,000 workers or more, 1947 to date

Month and year		Number of stoppages		Workers involved		Days idle	
		Beginning in month or year	In effect during month or year	Beginning in month or year (in thousands)	In effect during month (in thousands)	Number (in thousands)	Percent of estimated working time

Labor Month In Review

WORK EXPERIENCE. The Bureau of Labor Statistics published results of the latest survey on work experience of the population. The data are based on responses to special questions in the March 1982 *Current Population Survey*, conducted for BLS by the Census Bureau. The data show:

More extensive unemployment. The 23.4 million persons who encountered some unemployment in 1981 were 2 million more than in 1980, and represented 19.5 percent of all persons in the labor force for at least 1 week. This proportion was higher than the 18.1 percent in 1980, but below the 20.2-percent peak of 1975. For men and all blacks, however, the proportion with some unemployment during the year equaled or exceeded the previous highs.

Among men, the proportion with some unemployment during 1981 was 20.0 percent, the same as in 1975. Among women, the proportion was 19.0 percent, still below its 1975 peak of 20.5 percent. Men were not only more likely to become unemployed; they generally remained unemployed longer than women.

For blacks, the proportion experiencing joblessness in 1981—30.5 percent—was up from 28.0 percent in 1980 and even higher than the previous peak of 29.5 percent reached in 1975. By comparison, the proportion of whites with unemployment rose to 18.3 percent in 1981, up from 16.9 percent in 1980 but still down from 19.1 percent in 1975. For Hispanics, the rate remained largely unchanged over the year at 24 percent. Blacks were also unemployed longer than either whites or Hispanics. The median number of weeks of unemployment was 15.3 for blacks, 13.0 weeks for whites, and 14.5 weeks for Hispanics.

Of the 23.4 million persons who experienced some unemployment in 1981, 2.9 million held no job at all during the year—many because they left the labor force. Of the 20.5 million who found some work, the median duration of joblessness increased from 13.0 weeks in 1980 to 13.3 weeks in 1981. The proportion of unemployed workers with two or more periods of joblessness also increased in 1981 to 34 percent from 32 percent a year earlier.

A modest rise in employment. Employment continued to grow slowly in 1981. A total of 116.8 million persons 16 years of age and over worked all or part of the year, 1 million more than in 1980. Because population growth outpaced job growth, the proportion of the population working during the year edged downward for the third straight year to 68 percent.

For men, the proportion who worked continued a 15-year decline and—at 79.7 percent—reached its lowest level since the beginning of this series in 1948. For women, the proportion with employment was essentially unchanged and remained near the high of 58.0 percent reached in 1979. And the proportion of women working full time, year-round, continued to increase.

The proportion of blacks who worked during the year reached a new low of 60.7 percent. For black men, the proportion dropped to 68.6 percent, 4 percentage points lower than in 1978. The proportions of whites and Hispanics working during the year remained largely unchanged at 69 and 66 percent.

Lower real annual earnings. The median annual earnings of wage and salary workers employed at full-time jobs year-round rose to $20,593 for men and to $12,345 for women. For both groups, the 1981 median was about 9 percent higher than the median for the previous year. Thus, there was no change in the ratio of the average annual earnings of women to those of men, which remained at 60 percent.

After adjusting for inflation, the median annual earnings of men and women declined by about 1 percent relative to 1980, as the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W) rose by 10.2 percent in 1981.

Annual earnings of black and Hispanic workers continued to be much lower than those of white workers. The median for white men employed at full-time jobs all year was $21,087, compared to $14,988 for black men and $14,953 for Hispanic men. For white women who usually worked full time, year-round, the median was $12,476, compared to $11,166 for black women and $10,725 for Hispanic women.

The work experience questions in the March survey refer, retroactively, to respondents' work status and earnings for the entire previous year. Because many persons enter and leave the labor force during the course of a year, the total numbers with employment and unemployment as determined through the work experience questions are much greater than the annual averages based on the monthly survey conducted during the year. For example, the number who reported that they experienced some unemployment during 1981 was 2.8 times greater than the annual average of the 1981 monthly figures.

Tables showing the survey results appear in the news release, USDL 82-255, available from the Inquiries and Correspondence Section, Bureau of Labor Statistics, Washington, D.C. 20212. Survey results will be discussed in greater detail in a forthcoming issue of the *Review*. ☐

The Nation's employment situation worsens in the first half of 1982

The continued economic slide pushed the U.S. unemployment rate to a postwar high in the second quarter; construction and durable goods industries were hardest hit

MARILLYN A. HEWSON AND MICHAEL A. URQUHART

The economy entered 1982 deeply mired in its eighth post-World War II recession, following an unusually brief and weak recovery. The employment situation of some worker groups, particularly blacks and teenagers, had simply not shown improvement from the 1980 recession. Labor market conditions, which had been deteriorating rapidly since mid-1981, worsened substantially in the fourth quarter and continued to weaken through the first quarter of 1982. Employment dropped sharply and unemployment soared to the highest level recorded in the postwar era. However, there was evidence of moderation by the end of the second quarter.

Persistently high interest rates, which aborted the recovery from the 1980 recession, were a major cause of the 1981–82 economic reversal. The interest-rate sensitive construction and automobile manufacturing industries have experienced an economic slump spanning the two recessions. By late 1981, the weakness had clearly spread to much of the rest of the economy, including the services sector. The deterioration in the labor market became more pervasive as slackening sales and growing inventories forced firms to sharply curtail new orders, cut back production, and lay off workers. Although labor market conditions appeared to be improving by late spring, recessionary forces clearly dominated the first half of 1982.

This article continues the *Monthly Labor Review* practice of examining the Nation's employment situation at mid-year. It traces developments in employment and unemployment during the current recession, concentrating particularly on the first 6 months of 1982.

Job cutbacks

The renewed deterioration in economic activity worsened in the final quarter of 1981 and continued to accelerate during early 1982. However, signs that the rapid contraction in economic activity was losing momentum were evident by late spring, as the rate of decline in nonfarm employment slowed significantly in the second quarter. By midyear, nonfarm payroll jobs had declined by 1.4 million from the July 1981 high of 91.4 million.

To put the current labor market situation into perspective, it is useful to assess and compare the severity and extent of recent job cutbacks with those of the past. Table 1 presents measures of the duration, depth, and diffusion of declines in nonfarm payroll employment (based on data from the BLS survey of establishments) during each of the seven complete postwar recessions plus the current period.[1] April 1982 was used as the month that nonfarm payroll employment reached its trough for the 1981–82 recessionary period. Of course, data for subsequent months may prove otherwise, but it is still useful analytically to compare the de-

---

Marillyn A. Hewson is an economist in the Division of Monthly Industry Employment Statistics, and Michael A. Urquhart is an economist in the Division of Employment and Unemployment Analysis, Bureau of Labor Statistics.

cline in nonfarm payroll employment as of this point in the recession with past downturns.

As the table illustrates, the length of the contraction in nonfarm employment for the 1981–82 recession was longer than the declines for the three previous postwar recessions, spanning 9 months. Moreover, the pervasiveness of the 1981–82 decline, as measured by the 186-industries diffusion index which covers all employment on private nonagricultural payrolls,[2] was greater than for the 1980 downturn. While the 1980 contraction had been largely confined to construction and automobile manufacturing, and their supplying industries, the 1981–82 downturn was visibly more widespread, with employment declines witnessed in virtually all of the goods-producing industries, as well as in a large number of the service-producing industries.

Despite the longer and more pervasive nature of the recent nonfarm payroll job losses, the relative employment decline—1.4 percent—matched that of the 1980 downturn. Thus, the job loss total for each of the last two recessions was less than those that occurred in the 1973–75 and earlier postwar recessions.

It has been argued that the continuing shift in jobs from the goods to services sector has moderated the effects of business contractions on employment in the U.S. economy.[3] That is, as the service-producing sector's share of nonfarm jobs increases, this, in turn, serves to cushion a slowdown in the economy as a whole, because employment in the service-producing sector has historically been less affected by economic contractions than in the goods sector. Business downturns typically reduce the services sector's rate of growth but do not usually result in overall employment declines in services. This phenomenon was observed once again in the 1981–82 recession. Employment continued to expand in the services sector during the downturn as it has for most of the postwar recessions, although at a much slower pace than the roughly 4-percent growth rate experienced in nonrecessionary periods.

Table 1. Measures of duration, depth, and diffusion in peak-to-trough changes in nonfarm payroll employment, selected periods, 1948–82

Peak to trough[1]	Duration (in months)	Depth[2] (in percent)	Diffusion[3] (in percent)	
			30 industries[4]	186 industries
Sept. 1948 to Oct. 1949 . .	13	–5.2	90	([5])
June 1953 to Aug. 1954 . .	14	–3.5	87	([5])
July 1957 to May 1958 . . .	10	–4.2	88	([5])
Apr. 1960 to Feb. 1961 . . .	10	–2.2	82	([5])
Mar. 1970 to Nov. 1970 . .	8	–1.5	77	([5])
Oct. 1974 to Apr. 1975 . . .	6	–2.9	88	86
Mar. 1980 to July 1980 . .	4	–1.4	73	77
July 1981 to Apr. 1982[6] . .	9	–1.4	93	78

[1] Peak-to-trough dates in nonfarm payroll employment near the following National Bureau of Economic Research designated postwar recessionary periods: November 1948 to October 1949, July 1953 to May 1954, August 1957 to April 1958, April 1960 to February 1961, December 1969 to November 1970, November 1973 to March 1975, January 1980 to July 1980, July 1981 to –; the 1982 trough has not yet been designated by the National Bureau of Economic Research.

[2] Percent decline in employment level over the period.

[3] Percent of industries in which employment declined over a 6-month span, centered on the fourth month of the span: February 1949, March 1954, September 1957, August 1960, June 1970, January 1975, April 1980, and January 1982.

[4] Indexes of diffusion, 30 industries, 6-month span for April 1947 to May 1974 are published in John F. Early, "Introduction to Diffusion Indexes," *Employment and Earnings*, December 1974, p. 11, table 8. Indexes of diffusion for subsequent periods under study are for 29 industries due to the 1972 SIC revision which divided the industry category for Ordnance and accessories among the remaining manufacturing industries. These indexes were calculated specifically for this report.

[5] Data are not available.

[6] As of this writing, April was the month in which nonfarm payroll employment appeared to have reached its 1982 low.

The data in table 1 clearly show the moderation in recessionary employment cutbacks during the postwar period. In contrast to the employment effects of earlier recessions, job cutbacks during recent downturns have been generally shorter in duration and considerably less severe in magnitude. In fact, during the 1973–75 recession, which is generally regarded as the most severe postwar business downturn, the percentage decline in employment was significantly less than during postwar recessions prior to 1960, as well as noticeably shorter.

Although when examined as a separate entity the 1981–82 recession does not appear at this point to have resulted in employment declines any more severe than in previous downturns, it is worth noting two important factors which set it apart from other postwar recessions. The most significant atypical development was that this contraction was preceded by the shortest and weakest recovery in the postwar period, a recovery which halted before many industries had rebounded fully. As a result, some industries have experienced what may be regarded as a "double-dip" recession, a downturn more severe and spanning a much longer period than the cyclical decline for the economy in the aggregate. In fact, employment in some industries, such as primary metals and stone, clay, and glass, has fallen to levels below those experienced during the 1973–75 recession.

The second dominant feature was the failure of interest rates to recede as in previous postwar downturns. This caused a continued slump in the housing, automotive, and other credit-sensitive industries, and inhibited growth in all industries by reducing orders for suppliers, inflating inventory carrying costs, and dampening spending on consumer and capital goods.

As indicated above, the bulk of the employment declines in the first half of 1982 was centered in the goods-producing sector, notably in manufacturing and construction. (See table 2.) Continuing the losses begun in the second half of 1981, virtually every manufacturing industry registered some decline. The job losses took place largely in the more cyclically sensitive durable goods industries, where the job count fell by more than 900,000 between the second quarters of 1981 and 1982, principally the result of the depressed housing and automobile markets.

Housing demand both for new residential construction and for existing homes was kept low by high mort-

Federal	2,789	2,776	2,760	2,754	2,738	2,728
State and local	13,364	13,300	13,151	13,160	13,120	13,141

gage rates which prevailed throughout the period. Employment declines in the construction industry accelerated sharply in the last half of 1981 and first two quarters of 1982. Job cutbacks totaled more than 100,000 in the first 6 months of 1982, following a loss of almost 165,000 in the second half of 1981. With record inventories of unsold homes, the housing industry remained in its longest and deepest slump in postwar history.

The housing slump was also reflected in the dismal performance of industries producing household durables such as major appliances and household furniture. Likewise, lumber and wood products and stone, clay, and glass, which are also closely tied to the construction industry, were hard hit by the almost 3-year depression in the housing market.

The general economic malaise, coupled with high interest rates, prolonged the deep recessionary environment in the automotive industry. Reflecting the persistent weakness in the demand for autos, job curtailments in the transportation equipment industry approached 185,000 between the second quarters of 1981 and 1982. However, by mid-1982, automobile inventories appeared to have been worked down to minimal levels, and job cutbacks had slowed significantly.

The primary metals industry was another source of weakness in the durable goods sector. The recession-induced slowdown in demand and production prompted a widespread reduction in steel inventories by users concerned with the high cost of holding stocks. Moreover, a surge in steel imports also played havoc with the industry's already deteriorating operating environment. As a result, employment in primary metals dropped almost 190,000 over the year ended second-quarter 1982 to a level more than 160,000 below its 1973–75 recession low.

Sizable cutbacks were posted among the other durable metals industries—particularly fabricated metals, nonelectrical machinery, and electric and electronic equipment—affected by low capacity utilization, declining orders, and scaled-back capital spending plans. The pronounced slump in the automobile industry was a key contributor to the declines in nonelectrical machinery, particularly in the machine tools industry where scheduled major retooling programs were canceled or postponed when auto sales remained at depressed levels. High borrowing costs and the recession took their toll on nonelectrical farm and construction machinery, while softening crude oil prices dampened the demand for oil drilling equipment.

The adverse effects of the prolonged slump in the housing and automotive industries also spilled over into the nondurable goods sector. Particularly sharp employment declines were registered in the housing- and auto-related textiles and rubber and plastics products industries. The apparel industry, hurt by weak consumer spending and strong international competition, witnessed the largest curtailments, losing more than 90,000 jobs between the second quarters of 1981 and 1982. Both the apparel and textile industries have fallen to more depressed employment levels than those experienced during the 1973–75 recession.

Even the mining industry, which has generally been less affected by economic downturns subsequent to the 1973–74 oil embargo, witnessed employment declines in the first half of the year. Job losses in the metal mining and nonmetallic minerals industries were not offset, as in past recessions, by gains in the usually robust oil and gas extraction industry. The drop in world crude-oil prices was reflected in the job losses in oil and gas exploration and drilling activity in early 1982, where a 20,000 drop in employment in oil and gas field services in the second quarter contrasted sharply to the prior 8 years of steady growth. As a result, mining experienced a decline of 45,000 jobs in the first half of 1982.

Although the recessionary impact was primarily focused in the goods-producing sector of the economy, employment growth in the service-producing sector moderated significantly with the onset of the recession, and some of the industry divisions that were heretofore relatively recession-immune actually registered sizable job losses.

In government, employment continued the declines that began in mid-1980. State and local government employment, which historically has shown growth during periods of economic downturn, posted declines during the two latest business contractions. Conversely, Federal government employment has not been historically buoyant during recessions. For example, during the postwar recessions prior to 1980, Federal government employment declined, on average, by about 50,000, in contrast to an average increase of 300,000 jobs in State and local government. During the current downtrend, job losses in Federal government totaled 45,000 between July 1981 and April 1982, while State and local government employment fell 65,000.

Employment declines were witnessed in wholesale and retail trade by the end of 1981, due primarily to the lackluster performance of retail sales. Despite the appreciable abatement in inflation and consequent increased purchasing power, the general weakness in retail spending reflected consumer caution in light of the economic slump and uncertain job outlook. Thus, although trade employment turned up slightly in the first quarter of 1982, offsetting earlier declines, it registered little growth for the first half of 1982 as a whole.

The number of jobs in transportation and public utilities also displayed a noticeable decline, beginning in the final quarter of 1981. Employment dropped more than 55,000 by mid-1982, with job losses centered in transportation, primarily in railroads and trucking and warehousing. Transportation is the most cyclically sensitive of the service-producing industries, no doubt because of its strong dependence on activity in the goods-producing sector.

Countering the job losses in transportation, trade, and government, employment growth was sustained elsewhere in the service-producing sector, led by the services division. This includes industries ranging from hotels, amusement and recreation, and auto repair to legal, health, business, personal, and educational services. While increasing more than 400,000 between the second quarters of 1981 and 1982, the rate of job growth had slowed markedly from that experienced prior to the economic slowdown. Employment growth continued in the finance, insurance, and real estate industry but was also visibly affected by the recession, as it slowed to a trickle in the first half of 1982.

Worker groups

The impact of the recession is also clearly evident from recent movements in total employment as measured by the monthly Current Population Survey of households. (See table 2.) At 99.6 million in the first quarter of 1982, total employment was down 1.2 million from its pre-recession peak in the second quarter of 1981. However, the pace of the decline, quite rapid in the fourth quarter of 1981, had slowed in 1982, with employment increasing 200,000 in the second quarter.

The employment-population ratio, which measures the proportion of the population that is employed, is a useful statistic for placing these declines in perspective.[4] This ratio is sensitive to changes in both the number of jobholders and the number of persons in the working-age population. As such, it is an indicator of the economy's ability to provide jobs for its growing population. The following tabulation provides seasonally adjusted quarterly average employment-population ratios for the major age-sex groups for 1981 and 1982:

	1981				*1982*	
	I	*II*	*III*	*IV*	*I*	*II*
Total	58.4	58.6	58.3	57.8	57.3	57.3
Both sexes, 16 to 19 years	44.8	44.3	43.6	42.3	41.5	41.1
Men, 20 years and over	72.6	72.7	72.4	71.5	70.8	70.6
Women, 20 years and over	48.3	48.7	48.5	48.4	48.2	48.3

After reaching a high of 59.3 percent in the fourth quarter of 1979, two recessions in consecutive years reduced the overall ratio 2 points to 57.3 percent by the second quarter of 1982, a 5-year low. Although all three major age-sex groups registered employment-population ratio declines in the current recession, each drop depicts a slightly different predicament. For example, while employment among adult men fell by almost 700,000 to 53 million between the second quarters of

1981 and 1982, their population rose. Both of these factors would act to depress their employment-population ratio, which, in fact, fell to an alltime low of 70.6 percent in second-quarter 1982.

The situation for teenagers was also severe, as employment declines of 700,000 in the past year dropped their ratio 3 percentage points to 41.1 percent. This happened even though their population also decreased over the same period. That is, employment declines exceeded population declines. Unlike the case for men and teenagers, employment among women actually increased 370,000 over the year to 40 million in second-quarter 1982. However, because the number of women grew even faster, their employment-population ratio declined from a high of 48.7 percent in the second quarter of 1981 to 48.3 percent a year later.

The contrasting employment trends for men and women are attributable, in large part, to the nature of their occupational and industrial attachment. Cyclical downturns in employment are heavily concentrated in the goods-producing sector and thus among blue-collar workers, where the work force is predominantly male. Employment among blue-collar workers declined by 1.0 million in the last half of 1981, followed by an additional 800,000 drop in the first two quarters of 1982. Blue-collar employment was down to 29.9 million in the second quarter, the lowest in more than 5 years. While all major blue-collar occupations were affected, the operatives group, excluding transport, was the hardest hit, losing more than a million jobs. White-collar employment, on the other hand, actually increased by 500,000 between the second quarters of 1981 and 1982, with most of the increase occurring in 1982. Increases among professional and technical workers and salesworkers more than offset declines among clerical workers. Employment of service workers also increased slightly, but this was limited to the last half of 1981.

Divergent patterns of employment decline were observed among the different race-ethnic groups. White employment, which averaged 88.2 million in the second quarter of 1982, was off almost 1 million over the year. However, this decline occurred entirely in the latter half of 1981. Since December, their employment has increased slightly, although their employment-population ratio had slipped to 58.4 percent by the second quarter of 1982. In contrast, employment losses among blacks[5] and Hispanics have been greater in 1982 than during 1981. At 9.1 million in second-quarter 1982, black employment was 250,000 below the year-earlier level, and their employment ratio was at a record low. As in previous recessions, blacks have suffered proportionately larger employment declines than whites. Representing only 10 percent of the labor force, blacks have accounted for 24 percent of the total employment cutbacks. Hispanic employment actually increased during the early part of the recession, before declining 270,000 in 1982 to 5.2 million in the second quarter.

Record jobless rates reached

The continued economic slide in 1982 pushed the Nation's unemployment rate to a record high for the post-World War II period. Total unemployment reached 10.5 million, or 9.5 percent of the labor force, in May. This was an increase of 0.7 percentage point since December, and was 2.3 percentage points above the prerecession low of 7.2 percent recorded last July. Although less than the postwar average for peak-to-trough changes in the jobless rate of 3.3 percentage points, the current rate reflects, in part, the relatively brief and weak recovery that separated downturns in 2 consecutive years, an unprecedented economic occurrence. Unemployment had risen by 3.8 percentage points over these two recessionary periods, close to the 4.4 rise of the 1973–75 recession. The unemployment rate was unchanged in June.

After a surge in the last quarter of 1981 which added more than a million people to the jobless total, unemployment increased by less than half as much in the first quarter of 1982. However, while employment increased in the second quarter, the unemployment level jumped by another 850,000 persons, pushing virtually all major unemployment series to record rates. Following are the most recent and previous high monthly jobless rates, seasonally adjusted, for major demographic groups:

	1975	*1982*
Total	9.0 (May)	9.5 (May)
Both sexes, 16–19 years	20.9 (June)	23.1 (May)
Men, 20 years and over	7.3 (May)	8.7 (June)
Women, 20 years and over	8.5 (April)	8.3 (May)
Whites	8.4 (May)	8.5 (May)
Blacks	15.4 (Sept.)	18.7 (May)

Unemployment increased more rapidly for adult men than for women early in the recession; men's jobless rate, which typically is lower than that for women, actually exceeded the women's rate in the first and second quarters of 1982. (See table 3.) Overall, men have contributed about 65 percent of the total increase in unemployment since July 1981, and women, less than 30 percent. (Their respective shares of the labor force are 53 and 40 percent.)

The situation for teenagers was also quite severe. Their jobless rate showed no recovery during 1981 or 1982, rising almost 4.4 points from July 1981 to an alltime high of 23.1 percent in May 1982. Although teenagers accounted for only 8 percent of the labor force, their share of total unemployment was more than 19 percent. Black teenage unemployment was 50.1 percent in the second quarter of 1982, up more than 10 percentage points over the year. In contrast, white teenage unemployment increased about 3 points over the same period to 20.2 percent. Both rates surpassed those that occurred in the second quarter of 1975, the peak quarter in overall unemployment during the 1973–75 recession.

From a metropolitan-nonmetropolitan standpoint, it was apparent that black teenagers residing in the Nation's central cities and nonmetropolitan areas had been particularly hard hit in the current recession. This is illustrated in the tabulation below, which presents second-quarter 1975 and 1982 jobless rates (not seasonally adjusted) for metropolitan central cities and suburbs and for nonmetropolitan areas, by age and race:

	Central cities		*Suburbs*		*Nonmetropolitan areas*	
	1975 II	*1982 II*	*1975 II*	*1982 II*	*1975 II*	*1982 II*
White:						
16 to 19 years	21.2	21.5	18.4	18.7	16.6	22.0
20 years and over	7.7	7.3	6.5	6.5	6.6	7.9
Black:						
16 to 19 years	43.1	54.1	43.4	47.1	39.6	51.5
20 years and over	12.1	17.1	12.3	13.5	12.9	15.9

There was little change in the unemployment rate of black teenagers living in the suburbs over the same period. In contrast, all of the increase in unemployment among white teenagers occurred in nonmetropolitan areas.

Table 3. Major unemployment indicators, seasonally adjusted quarterly averages, 1981–82

[Unemployment rates]

Category	1981				1982	
	I	II	III	IV	I	II
Characteristic						
Total (all civilian workers)	7.4	7.4	7.4	8.3	8.8	9.5
Both sexes, 16–19 years	19.1	19.2	19.1	21.1	21.9	22.8
Males, 20 years and over	6.0	6.1	6.0	7.2	7.7	8.4
Females, 20 years and over	6.6	6.7	6.7	7.2	7.6	8.2
White	6.5	6.5	6.4	7.3	7.7	8.4
Black	14.6	15.1	15.8	17.0	17.4	18.4
Hispanic	11.0	9.8	9.8	11.1	12.4	12.5
Occupation						
White-collar workers	3.9	4.0	4.0	4.3	4.5	4.9
Professional and technical	2.7	2.9	2.7	2.9	3.1	3.3
Managers and administrators, except farm	2.5	2.6	2.7	2.9	2.9	3.5
Salesworkers	4.2	4.4	4.9	4.9	5.0	5.6
Clerical workers	5.6	5.6	5.7	6.1	6.6	6.9
Blue-collar workers	10.1	9.8	9.7	11.8	12.6	13.7
Craft and kindred workers	7.1	7.1	7.2	8.7	8.8	9.7
Operatives, except transport	12.0	11.5	11.3	14.1	15.6	16.7
Transport equipment operatives	8.9	8.1	8.0	9.6	10.3	11.8
Nonfarm laborers	14.7	14.1	14.0	16.2	17.6	18.5
Service workers	8.4	9.0	8.6	9.5	9.7	10.8
Farmworkers	5.0	5.1	4.7	6.3	5.8	7.1

Overall, unemployment among major race-ethnic groups increased substantially during the 1981–82 recession, with rates for whites and blacks at record levels in May 1982, while the rate for Hispanics was still slightly below its 1975 high. From July 1981 to May 1982, white unemployment was up 2.2 points to 8.5 percent. Blacks had a very limited recovery from the 1980 recession and began to experience record rates of unemployment almost from the beginning of the current downturn. Their rate was 18.7 percent in May 1982, up from 14.9 percent the previous July. Over the same period, Hispanic unemployment increased from 10.0 to 13.9 percent.

As indicated earlier, blue-collar workers have been hardest hit during the current recession. Unlike the total jobless rate, the blue-collar unemployment rate rose in June to 13.9 percent, up more than 4 points since July 1981. Operatives, excluding transport, and nonfarm laborers were most affected, with rates of 16.7 and 17.9 percent in June.

In contrast, white-collar workers showed only a moderate increase in unemployment over the year ended June 1982. Their rate of 5.0 percent in June was still below the highs of the 1975 recession. While unemployment increased for all major white-collar occupations, that for clerical workers showed the largest increase, rising 1.5 points to a high of 7.2 percent in April. Both service workers and farmworkers reached record rates in May of 11.3 percent and 8.3 percent, respectively.

Job losers, leavers, and entrants. During economic downturns, the number of persons who lose their jobs increases as firms cut back production and reduce their work forces through layoffs or permanent separations. At 58.0 percent in the second quarter of 1982, the job-loser share of unemployment was up about 7.5 percentage points over the year and surpassed the highs reached in both the 1975 and 1980 recessions. At about 19 percent during the first two quarters of 1982, the layoff component of the job-loser total was down slightly from the fourth quarter of 1981 and still below rates reached in the previous two recessions.

In contrast, the share of total unemployment that results from individuals voluntarily leaving their last jobs (to look for new jobs) tends to decline, as one would expect, during periods of high unemployment. The job leavers' share has declined throughout the current recession, reaching an alltime low of 8.4 percent in the second quarter of 1982. Both new entrants' and reentrants' shares of total unemployment were down slightly in the first 6 months of 1982.

Duration of unemployment. The substantial increase in unemployment during the fourth quarter of 1981 raised the short-term jobless share and reduced the two measures of duration of unemployment—the mean and the median. Since then both measures have lengthened as the proportion unemployed 15 weeks or longer exceeded 30 percent at midyear. The median duration of unemployment rose from 6.8 weeks in the fourth quarter of 1981 to a record 9.1 weeks in the second quarter of 1982. Over the same period, the mean duration increased from 13.2 to 15.1 weeks, surpassing the high reached during the 1980 recession but are still considerably below that reached in 1975. Because measures of duration typically lag cyclical changes in economic activity, both measures can be expected to continue rising for the balance of the year, even if an improvement in the labor market begins soon.

Other recessionary impacts

Shortened workweeks and discouraged workers. The poor performance of the economy over the past year has increased both the number of persons involuntarily working part time, either as a result of slack work or the inability to find full-time work, and the number reporting they want a job but are not looking for work because they believe no work is available—so-called "discouraged workers." Neither group is reflected in the official unemployment counts, although information on them is published on a regular basis. Measurement of both groups is vital to a fuller understanding of the nature and magnitude of the overall underutilization of our human resources. The following tabulation provides seasonally adjusted quarterly averages (in thousands) for nonagricultural workers involuntarily on shortened workweeks and for discouraged workers during 1981 and 1982:

	1981				*1982*	
	I	*II*	*III*	*IV*	*I*	*II*
Involuntary part-timers	4,323	4,166	4,460	5,108	5,450	5,680
As a percent of total at work	4.7	4.6	4.9	5.6	6.0	6.2
Discouraged	1,093	1,043	1,094	1,119	1,339	1,597

After declining in the second quarter of 1981, the number of nonagricultural workers involuntarily on part-time schedules increased steadily, reaching 5.7 million, or 6.2 percent of those "at work" in nonagricultural industries, in the second quarter of 1982; both figures are record highs since collection of the data began in 1955. While employers often reduce hours before laying off employees in economic downturns, the current high number of workers on shortened workweeks may also reflect a growing tendency among employers to keep workers on short workweeks for longer periods,[6] and the growing number of would-be full-time workers who obtain part-time jobs rather than remain unemployed.

The number of discouraged workers has risen nearly continuously for more than 3 years. The discouraged total reached a high of 1.5 million in the second quarter of 1982, up 375,000 since the end of 1981; about 70 percent of the discouraged cited job-market, rather than personal, factors as reasons for their discouragement.

Women and black and other minorities continued to be overrepresented among the discouraged in 1982. Women accounted for about 60 percent in the second quarter, whereas they comprised only 43 percent of the civilian labor force. While women's share of discouragement was the same as last year, the black and other minorities share has become even more disproportionate. Some 500,000 discouraged workers were blacks or members of other racial minority groups, 33 percent of the second quarter total and up from 31 percent a year earlier. (Their share of the civilian labor force was 13 percent.)

Alternative measures. While persons involuntarily working part time or discouraged are not included in the official measures of unemployment, the Bureau of Labor Statistics does provide a measure which includes these categories along with the unemployed. Designated as U-7, it is one of six alternative measures of unemployment regularly published by the Bureau; this has been done in recognition of the fact that no single measure of unemployment can satisfy the diverse needs of data users. The definitions for all seven measures are provided below, and their trends during the past decade are presented in chart 1.

U-1	Persons unemployed 15 weeks or longer as a percent of the civilian labor force.
U-2	Job losers as a percent of the civilian labor force.
U-3	Unemployed persons 25 years and over as a percent of the civilian labor force 25 years and over.
U-4	Unemployed full-time jobseekers as a percent of the full-time labor force.
U-5	Total unemployed as a percent of the civilian labor force (official measure).
U-6	Total full-time jobseekers plus half part-time jobseekers plus half total on part time for economic reasons, as a percent of the civilian labor force less half of the part-time labor force.
U-7	Total full-time jobseekers plus half part-time jobseekers plus half total on part time for economic reasons plus discouraged workers, as a percent of the civilian labor force plus discouraged workers less half of the part-time labor force.

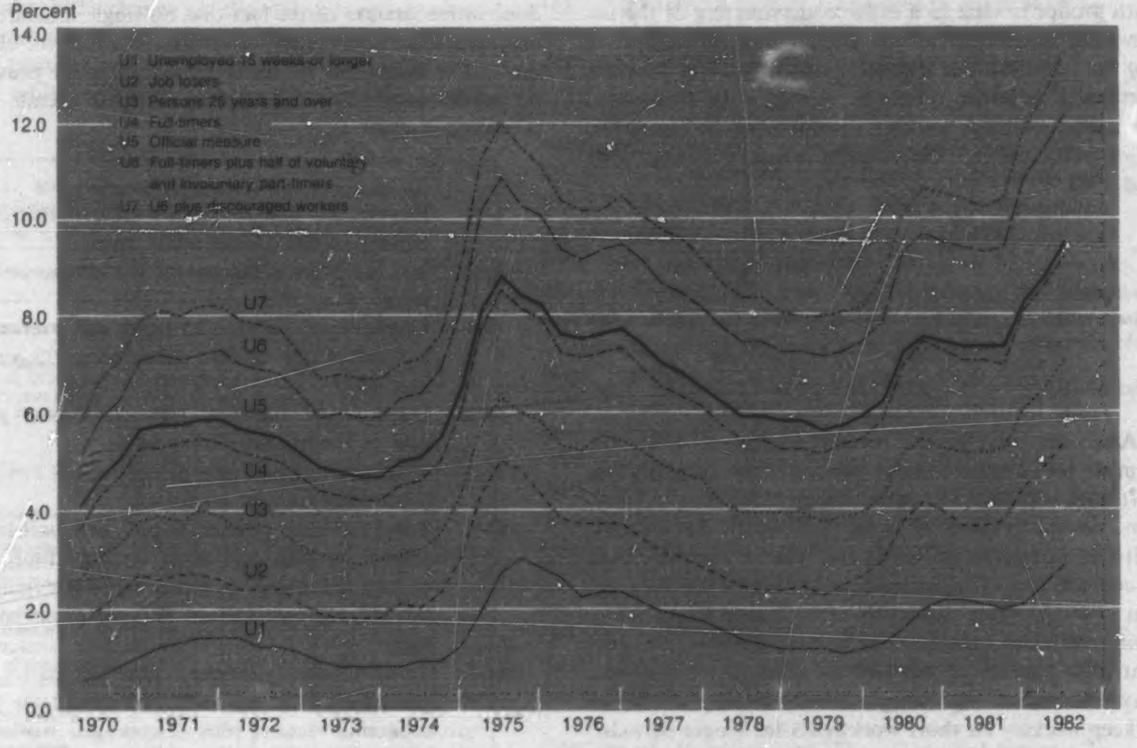
Each measure is representative of a different body of opinion about the meaning and measurement of unemployment. The rationale for U-7 is that involuntary part-time workers should be counted as at least "partially" unemployed and that the situation of discouraged workers is essentially the same as that of the unemployed. In this measure, those seeking only part-time work or voluntarily employed part time are given weight of one-half because the latter only work about half a full-time schedule. As can be seen from chart 1, U-7 has consistently been several points higher than U-5, the official measure. From a high of 12.0 percent in the second quarter of 1975, U-7 declined to 8.0 percent in the second quarter of 1979 before rising under the impact of the last two recessions to a new high of 13.4 percent in the second quarter of 1982.

In contrast, several measures are much more restrictive than the official measure. For instance, U-1 includes only those unemployed 15 weeks or longer, while U-2 counts only job losers. The rationale behind U-1 is that joblessness is a problem only when it has continued long enough to cause substantial hardship, while proponents of U-2 argue that only persons who lose their jobs merit concern because this is what leads to significantly lower income. In second-quarter 1982, U-1 was 3.0 percent, almost matching its high reached in 1975, while U-2 was at an alltime high of 5.5 percent.

Chart 1 shows how consistent the trend in unemployment has been, regardless of the measure one might choose. For example, all measures, with the single exception of U-1 which tends to lag the others by one or more quarters, reached cyclical highs in the second quarter of 1975 and lows in the second quarter of 1979. The magnitude of the impact of back-to-back recessions in 1980 and 1981–82 is evidenced by the fact that every measure reached a record high by the second quarter of 1982, with the exception of U-1.

Joblessness among States. There is considerable variation in unemployment rates at the State level as well as at other subnational levels. The reasons for such differ-

Chart 1. Unemployment indicators, seasonally adjusted quarterly averages, 1970-82



NOTE: Second-quarter 1982 data are April-May averages.

ences are numerous; those often cited include area differences in the composition of industry and the local work forces and a given area's competitive strength and growth rate.[7] The purpose here is not to examine why the incidence of unemployment varies across areas, but to present an overview of the States most or least affected by the recent downturn in economic activity. The uneven impact of the recent recession is reflected in the following list of States with the largest and smallest changes in jobless rates between the first quarters of 1981 and 1982; during that period, the Nation's unemployment rate increased 1.4 percentage points. (Data on the 10 most populous States come directly from the household survey, while data for the remaining States are based upon estimation procedures provided by the BLS to the States, taking into account data from the household survey, unemployment insurance records, and other sources.[8])

Increased substantially		*Little changed*	
State	*Percentage point change*	*State*	*Percentage point change*
Alabama	3.5	North Dakota	-0.9
Idaho	3.2	South Dakota	-0.4
Washington	3.1	New Mexico	-0.2
South Carolina	3.0	Wyoming	0.2
Iowa	3.0	Alaska	0.3
Indiana	2.7	New York	0.3
Michigan	2.6	West Virginia	0.3
Pennsylvania	2.6	Maine	0.4
		Nevada	0.4

In general, States with a heavy reliance on durable goods manufacturing such as auto, steel, and logging suffered the largest increases in unemployment, while mineral-rich States were less affected.

The following list of States with extremely high or low jobless rates (not seasonally adjusted) during the first quarter of 1982, when the overall rate was 9.5 percent, provides a slightly different picture:

Above 12 percent		*Below 6 percent*	
State	*Unemployment rate*	*State*	*Unemployment rate*
Michigan	16.4	Oklahoma	4.9
Alabama	14.3	Wyoming	4.9
Indiana	13.3	Kansas	5.4
Washington	12.7	Hawaii	5.7
Oregon	12.5	South Dakota	5.8
West Virginia	12.2	North Dakota	5.8
Ohio	12.1	Texas	5.8
Tennessee	12.1		

A comparison of the two tabulations shows that the four States with the highest jobless rates also posted substantial over-the-year unemployment gains. (The 12-percent cutoff point was chosen only to highlight the situation and is not meant to imply that any State does not necessarily have an unemployment problem.) Overall, the unemployment situation appears to be most severe in the industrial North and South Central States and in the Pacific Northwest, and least severe in the Plains and Mountain States.

Labor force growth

Growth in the civilian labor force has slowed considerably in recent years, in part because of the smaller number of persons reaching labor force age, but also because of the poor performance of the economy. At 110.2 million in the second quarter of 1982, the labor force had grown only 1.3 million over the year, far below the 2.1-million increase of the previous year. (Labor force movements within the second quarter were unusually large on a seasonally adjusted basis, as the total increased by a million in May and then declined by a similar amount in June.) The following tabulation provides seasonally adjusted labor force levels (in thousands) and participation rates (percent of a group's population that is either employed or unemployed) for the second quarters of 1981 and 1982 for major age-sex groups:

	Second quarter 1981		*Second quarter 1982*	
	Labor force	*Participation rate*	*Labor force*	*Participation rate*
Total	108,835	64.1	110,168	64.0
Both sexes, 16 to 19 years	9,084	55.8	8,569	54.1
Men, 20 years and over	57,243	79.2	57,920	78.9
Women, 20 years and over	42,507	52.3	43,629	52.8

Adult women continued to experience the strongest labor force growth—1.1 million over the year. In contrast, adult men posted an increase of only 500,000, while the teenage labor force declined by 500,000. Most of the teenage decline reflected the drop in their total population.

The overall labor force participation rate was 64.0 percent in the second quarter of 1982, about the same as the record 64.1 percent reached in the second quarter of 1981. The percentage of the population active in the labor force has been rising throughout the last two decades, as increases among adult women and, until recently, teenagers have more than offset declines among adult men.

In spite of the recession, the participation rate for adult women continued to increase, rising one-half of a point over the year to 52.8 percent. However, this was far below increases registered in previous years. At 78.9 percent in the second quarter of 1982, the participation rate for adult men continued its secular decline, while the rate for teenagers fell 1.7 points over the past year to 54.1 percent, its lowest level in more than 8 years.

BY MIDYEAR, there were some signs that the labor market was improving. Industry job cutbacks had slowed and unemployment appeared to be leveling. Whether the economy was actually on the road to recovery or merely pausing before further deterioration was still unclear, as economic signals overall were mixed. The behavior of interest rates, the factor that deepened and prolonged the current recession, will undoubtedly play the key role in the timing and degree of a subsequent recovery. □

[1] Statistics on nonagricultural payroll employment from the Current
Employment Statistics (CES) program are collected by State agencies
from employer reports of payroll records and are tabulated by the Bu-
reau of Labor Statistics. Data on labor force, total employment, and
unemployment are derived from the Current Population Survey
(CPS), a sample survey of households conducted and tabulated by the
Bureau of Census for the Bureau of Labor Statistics. A description of
the two surveys appears in the Bureau of Labor Statistics monthly
publication, *Employment and Earnings.*

[2] With the release of benchmarked employment data for the payroll
series in May 1982, the BLS converted coverage of the Indexes of Dif-
fusion from 172 to 186 industries, incorporating industry series added
with the 1972 SIC revision. For comparability, the 172-industries dif-
fusion indexes for the recessionary periods in table 1 are available be-
ginning with the 1960–61 period. The indexes showing the percent of
industries in which employment declined over a 6-month span are as
follows: August 1960, 76; June 1970, 76; January 1975, 88 April
1980, 78; and January 1982, 79. The 186-industries indexes were not
much different from the 172-industries indexes for the same time peri-
ods. For a detailed discussion of indexes of diffusion of changes in the
number of employees on private nonagricultural payrolls, see John F.
Early, "Introduction of Diffusion Indexes," *Employment and Earnings,*
December 1974, pp. 7–11.

indicator, see Carol Boyd Leon, "The employment-population ratio:
its value in labor force analysis," *Monthly Labor Review,* February
1981, pp. 36–45; and Julius Shiskin, "Employment and unemploy-
ment: the doughnut or the hole?" *Monthly Labor Review,* February
1976, pp. 3–10.

[5] The proportion of blacks in the "black and other" group has been
declining; it was 83 percent in 1980. This has resulted from a gradual
influx of Asians, particularly Vietnamese, into the U.S. labor force in
the 1970's. For this reason, and because of the availability and in-
creased reliability of data for blacks, it is not as necessary as in the
past to use data for "black and other" when discussing black work-
ers. Thus, unless otherwise stated, the term black in this article refers
exclusively to the "black only" population and not to the "black and
other" category, which, in addition to blacks, includes American
Indians, Alaskan Natives, and Asian and Pacific Islanders.

December, 1978, pp. 35–53; Lynn E. Browne, "Regional Unemploy-
ment Rates—Why Are They So Different?" *New England Economic*
Review, July/August 1978, pp. 5–26; and Thomas Hyclak and David
Lynch, "An Empirical Analysis of State Unemployment Rates in the
1970's," *Journal of Regional Science,* Vol. 20, No. 3, 1980, pp. 377–
86.

[8] Labor force and unemployment estimates for States are part of a
cooperative program between the Bureau and State employment secu-
rity agencies where estimates are prepared under concepts, definitions,
and technical procedures established by the Bureau. A fuller explana-
tion of the technical procedures used to develop these estimates ap-
pears monthly in the Explanatory Note on State and Area Un-
employment Data in the BLS periodical, *Employment and Earnings.*
The 10 most populous States (as of the 1970 census) for which esti-
mates come directly from the Current Population Survey are: New
York, California, Illinois, Ohio, New Jersey, Pennsylvania, Michigan,
Texas, Massachusetts, and Florida.

Imports and domestic employment: identifying affected industries

For its trade monitoring program, the Bureau has developed measures of import penetration; initial data suggest about one-fourth of manufacturing groups might be sensitive to rising imports

GREGORY K. SCHOEPFLE

Concern about the performance of U.S. industries in domestic and international markets has led to increasing interest in the development of indicators of the domestic market share accounted for by imports. Accordingly, the Bureau of Labor Statistics has begun constructing measures which, when applied in conjunction with other information, could be used to identify domestic industries that might be experiencing adverse employment effects or other adjustment problems because of changing international trade patterns. Analysis of the geographic concentration of domestic production and employment for these sectors could help Federal agencies target assistance programs for workers, communities, and industries.

This article considers the problems of constructing indicators of import market share at the 4-digit Standard Industrial Classification (SIC) level,[1] and discusses some of the main features and trends of the BLS trade monitoring statistics. Data examined so far show that, between 1972 and 1979, the import share of the domestic market for manufactured goods rose moderately. However, among the 318 manufacturing groups studied separately, 72 were found to be "import-sensitive"—that is, having experienced either a sustained high level or a substantial increase in import share of U.S. sales during 1972–79. Employment declines over this period were reported in 38 of the 79 domestic industries which produce products similar to those in "import-sensitive" groups; more than half of these 38 industries were involved in the manufacture of textile, apparel, and leather goods products. The limitations of these measures are examined in the appendix.

Background

Under section 282 of the Trade Act of 1974 (19 USC 2393), the Bureau of Labor Statistics and the Bureau of the Census were given the responsibility of monitoring changes in U.S. imports and related domestic production and employment. The context for this monitoring program was the expanded trade adjustment assistance program established under Title II of the act. The trade monitoring system was intended to inform the Congress and administrators of adjustment assistance programs of those industries and localities in which adjustment

---

Gregory K. Schoepfle is a supervisory economist in the Division of Foreign Labor Statistics and Trade, Bureau of Labor Statistics. This article is based on a paper the author presented at the Annual Meeting of the Western Economic Association in San Francisco, July 5, 1981. Mary Kay Rieg of the *Review* staff provided special editorial assistance.

problems were likely to occur as a result of the expansion of international trade.

The Bureau of the Census and the Bureau of Labor Statistics (BLS) jointly carry out the monitoring. The Census Bureau develops and publishes trade and domestic production data, while BLS has chief responsibility for the development and publication of related employment data, the development of the trade monitoring system, and the establishment of a reporting program on the results.

In connection with its broad responsibility, BLS plans, subject to availability of resources,[2] to:

- Establish a reliable base of detailed merchandise import, product-based output, and industry employment data on a consistent classification system.
- Set up a timely system for reporting and summarizing the data.
- Provide objective interpretations of the findings.

Currently, the Bureau produces quarterly and annual tabulations on SIC-based merchandise imports and industry employment. Import penetration ratios, that is, the ratio of imports to the sum of domestic product shipments and imports, are computed annually for manufacturing commodity groups.

Concepts

A variety of measures can be developed to assess the United States' relative trade performance, both on an aggregate basis and by industrial sector. Depending upon the ultimate application, certain definitions of these measures may be preferred over others. Of special interest for the examination of potential employment adjustment problems are indicators of the share of the domestic market accounted for by foreign imports and the share of total sales which is accounted for by U.S. exports.

Ideally, a measure of import penetration should compare domestic consumption of a product with imports of the product at a specified market point of distribution; however, no product-specific measure of consumption exists. The best available substitute is domestic demand, often termed "apparent consumption," which is usually defined as U.S. sales (shipments) less net exports (exports minus imports).[3] Furthermore, while final sales (retail for consumers) of imports over final U.S. sales from all sources would be the most appropriate measure of the proportion of the domestic market served by imports (that is, import penetration), such data are not reported separately in Federal statistics.

Similar problems arise in the development of measures of export performance. Final sales of U.S. exports (excluding transportation and insurance costs to the point of exportation) over U.S. total final sales would be the best measure of the proportion of domestic economic activity accounted for by the exports; unfortunately, data on export sales by U.S. manufacturing
establishments are limited.[4]

Import penetration and export proportion measure
presented in this article show the market shares of a fi
nal commodity which are accounted for by imports an
exports, respectively. They do not, however, account fo
intermediate products used in domestic production. Fo
example, they exclude imported or domestically pr
duced components of end-products which are consume
here or abroad. An analysis of intermediate goo
would have to be based on an econometric model or a
input-output table.

Taking into account the data limitations which a
discussed in greater detail in the appendix and the d
sire to develop measures for broad industrial tra
monitoring, currently available series on U.S. impo
and exports, reclassified to the equivalent producer i
dustry, are related to industrial product-based sh
ments. Four ratios which relate domestic shipments
international merchandise trade may be considered:[5]

(a) $M / (M + S - X)$

(b) $M / (M + S)$

(c) X / S

(d) $X / (M + S)$

where

M = U.S. imports
X = U.S. exports
S = U.S. product shipments
$S - X$ = consumption of domestic produced goods
$M + S - X$ = apparent consumption
$M + S$ = new supply

Measure (a), the ratio of imports to apparent
sumption, is commonly used to assess the import p
tration of a domestic market, showing the share
market which is served by imports. One shortcomi
this market share-based measure from an employ
point of view is that it fails to capture the offsettin
ture of the domestic industry's involvement in e
markets. Measure (b) makes allowances for this f
representing the ratio of imports to new supply.
supply is defined as imports plus U.S. product
ments. The latter include domestically produced
which are exported for foreign consumption as w
those which are consumed here. Such a supply-
measure takes into account (and is influenced b
only domestic demand but also foreign demand fo
goods. Increased output in response to increases
ther domestic or foreign demand for the produc

usually result in increased domestic employment levels. Therefore, from an employment point of view, measure (b) might be preferred to (a), because it takes into account the foreign demand for U.S. goods. If exports do not play a significant role in the consumption of an industry's output, then ratios (a) and (b) will be nearly the same. However, if exports are important, ratio (b) will be smaller than (a).

Measure (c), the ratio of exports to U.S. shipments, is a commonly used export performance measure. It reflects the proportion of total domestic output which is exported, but fails to capture the influence of imports in U.S. markets. Measure (d), the ratio of exports to new supply, accounts for the influence of imports and possible displacement effects which they might have. From an employment standpoint, any domestic employment displacement due to imports would be conjectural—that is, it is not clear that the same goods could or would be produced domestically if imports were not available.[6] Therefore, measure (c) might be preferred to (d), because it would directly reflect the actual importance of exports in domestic activities. Ratio (d) will be smaller than (c) if imports are significant; correspondingly, the less significant imports are in new supply, the closer the two measures will be.

Ratio (d) does have a feature which might commend its use in conjunction with measure (b), namely a common denominator. Hence, the difference between measures (d) and (b) could be viewed as a trade gap or balance measure for a sector relative to the size of the sector.

All of the above ratios could be based on either dollar value or a unit of quantity, if a consistent measure of the latter is available. (Perhaps the best evaluation of these ratios from an employment standpoint would be with weighted aggregates of U.S. unit labor requirements.) Measures based on quantity assume that there is a homogeneous and meaningful unit as well as product specification for the classification. For certain well-defined products, such as new automobiles and textile goods, quantity-based measures might be constructed, but the appropriate level of commodity aggregation is often difficult to determine. Furthermore, quantity-based measures often fail to capture quality differences within a product group.

In constructing product-based measures at the aggregate industrial level, value-based measures, while they have some limitations,[7] are generally more useful, because homogeneous units of quantity either are not available or are not very meaningful for purposes of comparison. About two-thirds of the manufacturing 4-digit SIC-based import commodity groups do not have a homogeneous unit of quantity.

Quality differentials are frequently reflected in value data through prices, which may serve as implicit weights when aggregating commodity groups. Ideally, the value of imports should be adjusted for price changes, as well as for importer markups, customs duties, subsidies, and costs of transportation and insurance to the market point of distribution. A transaction-based price index would account for any changes in product specification, quality, and conditions of sale. Unfortunately, at the present time, there are no adequate and consistent deflators for SIC-based imports or exports. In general, domestic prices of imported goods include, in addition to the import price, the domestic value added (unloading, inland transit, further manufacture, handling, markups, and so forth) and applicable duties. Because all these costs can vary independently of import prices, domestic price trends are considered to be poor proxies for import price trends.[8] In addition, the use of calculated import unit-value measures as price indexes for import commodity groups can be misleading, because of variations in product specification and quality within the product category.

In general, value-based measures will differ from those calculated on a quantity basis. For example, value-based import penetration ratios will be smaller than those which are quantity based in those cases where imports consist predominantly of items with lower unit values than similar domestic products (for example, nonrubber footwear and brassieres). The effect of using current-dollar trade and shipment values in place of real (deflated) values in the calculation of the market share measures depends upon the stability of the ratio of import or export prices to domestic prices. In many cases, we would expect domestic and world commodity prices to exhibit similar trends in the absence of domestic price controls or government subsidies. Therefore, it would be expected that import penetration ratios based on current-dollar values would show more stability with regard to inflation than either of their component value-based series on imports or shipments.

Table 1. Two-digit SIC-based share of manufacturing total imports, shipments, and employment, by import penetration level, 1972 and 1979

[In percent]

Data

The shipments data for the market-share measures are from the Census Bureau's *Annual Survey of Manufactures*. The value of product shipments is a sampling estimate of the current-dollar value of all products sold, transferred to other plants of the same company, or shipped on consignment, whether for domestic consumption or for export. It represents net sales value (f.o.b. plant), and excludes discounts and allowances, freight charges, and excise taxes. In a few cases, domestic production values, rather than shipment values, are used. Products bought and resold without further manufacture are excluded. The value of shipments for a 4-digit class of products used in the measures is on a wherever-made basis—that is, total shipments of the primary products of the industry, which include sales of the same products made by firms classified in other industries. (See the appendix for further discussion.)

The import and export data are from the Census Bureau's foreign trade statistics.[9] The import value is current U.S. dollar customs value (usually foreign port value) of imports for consumption and excludes any customs duty, freight, or handling charges. The export value is current U.S. dollar free alongside ship (f.a.s.) value (U.S. port value) of exports of domestic merchandise and includes any markups and freight or handling charges incurred to the port of exportation.

Trends in penetration measures

As part of the current trade monitoring program, BLS tracks 347 4-digit SIC-based manufacturing import groups (as well as 63 agricultural and mineral groups) each quarter for significant increases in the current-dollar value of imports for consumption. In addition, industry employment is analyzed quarterly for significant declines.

While these procedures are useful in highlighting short-term movements in those commodity groups and industries which are experiencing a sudden increase in imports and a decline in current industry employment, it is instructive to consider the structure and composition of import penetration, as well as the long-term trends in industry employment, for those commodity groups for which either import penetration has increased substantially in the recent past or the level of penetration has remained relatively high.

Structure and composition. Chart 1 presents an overview of the structure of import penetration and export proportion in 2-digit SIC-based U.S. manufacturing major groups for the years 1972 and 1979 (latest available). In both years, the all-manufacturing levels of both import penetration and export proportion were in the 5.0- to 9.9-percent range; between those years, import penetration rose more moderately than export proportion. During the period 1972–79, the leather, miscellaneous manufactures, and apparel major groups experienced the largest increases in import penetration, while the textiles group registered a slight decline. During the same period, the tobacco, instruments, electrical and nonelectrical machinery, and miscellaneous manufactures major groups showed the largest increases in export proportion, while the petroleum refining group experienced a modest decrease.

At the aggregate level, imports appear to contribute significantly (above 10 percent in 1979) to the available new supply of apparel, lumber, leather, primary metals, electrical machinery, transportation equipment, instruments, and miscellaneous manufactures, but have a negligible role in tobacco and printing and publishing. In four of the major groups in which imports contribute significantly to new supply (transportation equipment, electrical machinery, instruments, and miscellaneous manufactures), U.S. exports also play an important role. Other major groups in which a significant proportion of output is exported include tobacco, chemicals, and nonelectrical machinery.

Table 1 presents the percentage distribution of total manufactures import value, product-based shipments, and industry employment by import penetration level in 1972 and 1979, on a 2-digit SIC basis. In both years, 12 of the 20 major manufacturing groups had a level of import penetration of 5 percent or more. In 1972, the corresponding imports accounted for 79 percent of the value of all manufactured imports; by 1979, their imports accounted for about 83 percent of the total.

In 1972, approximately 29 percent of the import value was accounted for by product groups with penetration levels of 10 percent or more, but by 1979, this share had grown to nearly 58 percent. During this period, both the industry employment and product shipments share-of-manufacturing total for the groups with

NOTE: Due to rounding, sum of individual items may not equal total.

penetration levels of 5 percent or more remained relatively unchanged, in the 58- to 66-percent range. Despite the probability of extensive duplication in the value of product shipments at the 2-digit SIC level, the shipments value share-of-manufacturing total for groups with 1979 penetration levels of 5 percent or more was about 60 percent, whether measured on a final product, industry, or value-added basis.

Table 2 shows the percentage distribution of total manufactures import value and product-based shipments by import penetration level in 1972 and 1979 on a more detailed 4-digit SIC basis. Tables 3 and 4 present some additional information on the 1972 and 1979 distribution of 4-digit SIC-based manufacturing commodity groups by import value and import penetration level.

In 1972, 40 percent of the 318 4-digit product groups had levels of import penetration of 5 percent or more; these product groups accounted for 81 percent of the value of manufactures imports and 37 percent of the value of manufactures product shipments. By 1979, 53 percent of the groups had a penetration level of 5 percent or more and accounted for 90 percent of the value of manufactures imports and 56 percent of manufactures product shipments. While the number of groups, import value, and shipments value share-of-manufacturing totals for 4-digit groups with import penetration levels between 2.0 and 19.9 percent remained fairly stable between 1972 and 1979, the share distribution within this penetration range reflected a general upward trend because of the growing importance of imports in new supply. For example, during this period, the share-of-manufacturing total of those 4-digit groups with import penetration levels between 10.0 and 19.9 percent increased 4.7 percentage points to 16.0 percent, while the share of groups with import penetration levels between 2.0 and 4.9 percent decreased 6.6 points to 19.8 percent.

In 1972, slightly more than one-fourth (86 out of 318) of the 4-digit manufacturing commodity groups had levels of import penetration less than 10 percent and import values under $10 million. (See table 4.) By 1979, the number was only one-ninth of the total number of groups. Between 1972 and 1979, the number of 4-digit commodity groups with import values of $500 million or more increased about 350 percent, from 13 to 58.

To permit examination of the composition of changes within the major manufacturing groups over time, table 5 summarizes the distribution of 4-digit manufacturing commodity groups within each 2-digit major manufacturing group, by 1972 and 1979 import penetration level. Perusal of this table reveals that the 2-digit major

[1] Level of import penetration for the 2-digit SIC-based group in 1972 or 1979.

group import penetration level, while representative for the group as a whole, does not reflect the level of penetration for each 4-digit group within the major group. In addition, the 4-digit industry size, importance (based on shipments value or employment), and propensity to import or export varies greatly within some 2-digit major groups.

For example, in 1979, 53 percent of all 4-digit manufacturing commodity groups had a level of import penetration of 5 percent or more. Sixty percent—12 of 20—of the 2-digit major groups had overall levels of import penetration of 5 percent or more. Two of these 12 major groups (paper and petroleum refining) had fewer than 50 percent of their constituent 4-digit groups with penetration at or above the 5-percent level. Conversely, in one 2-digit major group (stone, clay, and glass) with a penetration level less than 5 percent, more than 50 percent of component 4-digit groups experienced penetration levels of 5 percent or more.

Long-term trends. The following tabulation compares the 1972–79 average annual increases in import penetration with the average levels of penetration for all 4-digit SIC-based manufacturing groups:

	Total groups	*Average annual change: Under 1 percentage point*	*1 percentage point or more*
Total groups	318	274	44
Average level:			
Under 15 percent	266	246	20
15 percent or more	52	28	24

As indicated, 44 of the 318 4-digit manufacturing commodity groups had a 1972–79 average annual increase in import penetration of 1 percentage point or more. (See table 6.) Twenty of the 44 groups had a 1972–79 average level of import penetration of less than 15 percent. During this same period, 5 of the 44 groups experienced a rate of growth in export proportion which equaled or exceeded that of import penetration. Fifty-two of the 318 manufacturing commodity groups had a 1972–79 average level of import penetration of 15 percent or more. (See table 7.) In 28 of these 52 groups, import penetration either declined or had a 1972–79 average annual increase of less than 1 percentage point. Of the 52 groups, 15 exported at least 10 percent of their shipments, on average, during this period, indicating a high degree of trade activity in both imports and exports.

If we consider those groups for which either (1) the 1972–79 average annual increase was 1 percentage point or more, or (2) the 1972–79 average level of import penetration was 15 percent or more, we obtain a total of 72 import groups which have recently experienced either a sustained high level of import penetration or substantial increase in import penetration. For brevity, we shall refer to these 72 import groups as "import-sensitive" groups.[10]

Industry employment related to the "import-sensitive" groups is presented in table 8. In many cases, the

[1] The 1972–79 average annual percentage point change in export proportion for this group is equal to or exceeds the 1972–79 average annual percentage point change in import penetration.

nes = not elsewhere specified.

industry employment series are not that well matched to the import groups. The industry coverage may be broader or narrower than that implied by the import product group; some industry employment series are related to more than one import group. Given these and other limitations which are discussed in the appendix, the employment coverage of the "import-sensitive" groups presented in table 8 should be considered only as approximate.

Fifty-one industry employment series in table 8 relate

Table 7. Four-digit SIC-based manufacturing commodity groups with average levels of import penetration of 15 percent or more, 1972–79

SIC-based code	Commodity group	Imports as a percent of new supply					Average annual percentage point change, 1972–79

[1] Import commodity groups for which either (1) the 1972-79 average annual increase in import penetration was 1 percentage point or more, or (2) the 1972-79 average level of import penetration was 15 percent or more.

[2] Unpublished establishment survey data. Employment data are of good quality, but have not been published due to an inadequate sample for publication of non-employment data types.

[3] Industry employment series is related to more than one import-sensitive product group.

[4] Unpublished establishment survey data. Employment data are of low quality and have not been published due to an inadequate sample for publication of any data types.

[5] Unpublished establishment survey data. Employment data represent a combination of unpublished confidential series to avoid disclosure of any individual industry estimates.

nec = not elsewhere classified.

NOTE: There are a few industry employment series which have not been included because either data are not available for 1972 or industry coverage of the employment series is too broad to be matched with the import-sensitive product group.

SOURCE: Bureau of Labor Statistics, Payroll Employment Program, Establishment Survey, March 1981 benchmark.

to the 44 import commodity groups in table 6 with 1972–79 average annual increases in import penetration of 1 percentage point or more; 28 industry employment series relate to the 28 import groups in table 7 that had 1972–79 average annual increases in import penetration of less than 1 percentage point, but an average level of import penetration of 15 percent or more.

Of the 79 employment series in table 8, 38 show a declining 1972–79 average annual rate of change; 51 show a declining rate for the period 1972–81. (The larger number of declines for the 1972–81 period may be due to the downturn in the business cycle during 1980.) Twenty-two of the 38 industries with 1972–79 employment declines and 27 of the 51 with 1972–81 employment declines are in the textile, apparel, and leather goods groups. During the period 1972–79, total manufacturing employment grew at an average annual rate of 1.4 percent; for the period 1972–81, the growth rate was 0.6 percent. Further analysis would be required to determine whether imports were the major factor in the long-term employment decline in these 38 (or 51) industries. However, the foregoing does illustrate how analysis of import penetration and change in industry employment might be used as a screening tool to focus on potential import problems which an industry might be facing.

Usefulness of the measures

A review of some of the major methodological and measurement problems in relating trade data to domestic output and industry employment is presented in the appendix. Given these problems, the absolute values of the measures of import penetration and export proportion are of limited use, for example, in inter-industry comparisons. However, they are valid for the study of direction and magnitude of change over time, if all other relevant factors remain unaltered (for example, no structural or reporting changes).

Changes in import penetration are usually more important than levels when examining for possible employment displacement in a particular industry. However, it should be noted that a rapid rise in import penetration is not necessarily undesirable, because it might reflect a greater product specialization within an industry. This might involve higher levels of both imports and exports, reflecting greater net competitiveness. For this reason, measures of import penetration should be examined in conjunction with measures of export proportion as well as other indicators.

The BLS measures of import penetration have been developed on a 4-digit SIC basis because domestic employment measures are available only on that basis. However, by confining import penetration measures to the 4-digit SIC level, which often represents combinations of broad product groups, we may overlook some potential adjustment problems if these groups contain a mixture of very competitive and less competitive products.

AS MORE COMPLETE DATA become available, it may be possible to further refine and improve the quality of the measures which BLS has developed for use in its trade monitoring program. However, the interpretation of import penetration measures may be affected by factors in addition to the data limitations indicated above. For example, the stage of the business cycle, as reflected in U.S. and world demand, will help determine the level and composition of both imports and exports. Shifts in consumer demand due to changing tastes or product substitution, strikes, the weather, and new government regulations are other exogenous factors. Long-term secular changes in capital investment, technology, and labor force characteristics also are influential. ☐

FOOTNOTES

[1] Commodity classification is based upon the *Standard Industrial Classification Manual: 1972* (Washington, U.S. Government Printing Office), and its 1977 Supplement. See the appendix for a more detailed description of the methods used to classify imports, exports, and domestic output.

[2] While BLS has received no appropriation for its role, it has devoted some resources from other programs to trade monitoring. The Census Bureau has received some limited funding for its role which has resulted in improved comparability between reported domestic production, import, and export commodity data, as well as more timely and detailed reporting of domestic production data.

[3] An alternative measure might be based upon a production or output basis, that is, imports relative to shipments less net inventories and net exports. In most cases, inventory change data are not generally available for adjusting product shipments data. If this measure were based over several years, the year-to-year fluctuations in inventories over the business cycle probably would not create severe distortions and would likely parallel analysis based on a domestic demand or apparent consumption basis.

[4] See, "Origin of Exports of Manufacturing Establishments," in *1976 Annual Survey of Manufactures*, M76-AS-8 (Bureau of the Census, 1978).

[5] A fifth measure, the ratio of imports to U.S. product shipments, M/S, is not discussed here. This ratio is equivalent to the ratio of the relative shares of new supply of imports-to-shipments, that is, $[M/(M+S)]/[S/(M+S)]$. Algebraically, it can be derived from ratio (b) as follows: let $M/(M+S) = B$, then $M/S = B/(1-B)$. Note that B may take on any value between 0 and 1; (M/S) is nonnegative but not necessarily bounded from above.

[6] A solution to this problem would involve distinguishing "directly competitive" imports (primarily finished manufactures) from "supporting" imports such as raw materials (for example, petroleum, lumber, certain mineral and agricultural products, and semi-finished manufactures), and analyzing the supply and product availability of domestically produced substitutes. Substitution of domestic goods for foreign goods and resources will depend on both consumer tastes and industry technology. On the consumer side, income and price (cross) elasticities of demand, and on the producer side, capacity utilization,

productivity, and the possibility of resource bottlenecks, will influence the adjustment (both in the short run and the long run) to replacement of imported commodities with domestically produced goods.

[7] The value-based measures presented in this article should be considered as approximations intended for broad industrial monitoring. Further adjustments would need to be made for a detailed analysis of a specific sector. These might include adjustments in import value to make it more equivalent to a domestic valuation, and attempting to account for different cost and wage structures among countries, the changing composition of the product basket, point of sale, and timing of sale.

[8] BLS produces U.S. import and export price indexes which are based on the nomenclature of the Standard International Trade Classification (SITC) System of the United Nations, 1974 Revision. Monthly net transaction price data are collected by BLS for approximately 14,500 products from more than 6,000 companies (importers and exporters). The product areas surveyed for the import price indexes account for about 96 percent of the value of U.S. imports and cover all imported commodities, excluding chemicals. The product areas surveyed for the export price indexes account for approximately 64 percent of the value of all U.S. exports and include machinery and transportation equipment, and selected categories of chemicals, intermediate products, crude materials, and food.

[9] Import data are BLS SIC-based aggregations of Census Bureau IM-145 monthly import tapes. Export data are from the Census Bureau's EA-675, U.S. Exports of Domestic and Foreign Merchandise, SIC Division by SIC-Based 2-Digit, 3-Digit, and 4-Digit Product Code.

[10] It should not be concluded that the remaining 246 groups are insensitive to import changes. The choice of average annual increase of 1 percentage point and average level of 15 percent for the period is completely arbitrary and made only for the purpose of reducing the number of groups considered for analysis. The selection criteria could be adjusted according to any desired level of discrimination.

APPENDIX: Data limitations

There are several conceptual and measurement difficulties in comparing domestic output and employment data to commodity trade data. These problems vary with the product or industry considered, the definition of the industrial market, and the scope of the measure. Because each of the factors enumerated below affects comparability among trade and domestic data to some degree, the BLS measures of import penetration and any related employment coverage for import groups should be viewed only as approximations.

Market mismatches. For the analysis of trade-related employment effects, it would seem reasonable to consider the output at the industrial level (4-digit SIC), because workers usually are mobile between establishments which produce similar products. However, for any meaningful analysis, there must be a defined market with distinct products, the definition depending, in part, upon the degree of vertical integration within the industry. In the above article, markets were defined at the industry level (4-digit SIC), but the pertinent market could be broader in some cases (for example, steel—SIC 331) or narrower (as for canned mushrooms, SIC 20333, within canned vegetables, SIC 2033). This is an important caveat, because the degree of import penetration calculated will vary with the definition of the 'industry' (2- , 3- , or 4-digit) or product category (5- or 7-digit) used.

Commodity versus industry base. Data on U.S. manufacturers' shipments are available on two bases: 1) industry shipments—total shipments of firms classified in a given industry, which include other secondary products, and 2) product-class shipments—total shipments of the primary products of the industry, which include sales of the same products made by firms classified in other industries. Because international trade classifications are commodity-based, it was decided to match imports and exports to domestic sales of a commodity on a product-class basis.

A product class is a group of individual products of an industry. It is designated by a 5-digit code, the first four digits indicating the SIC (industry), and the fifth, the specific group of products. In some cases, a 5-digit product class is, by definition, limited to products of a particular manufacturing process (for example, ferrous wire made in wiredrawing plants, SIC 33151, as distinguished from ferrous wire not produced by wiredrawers, SIC 34961). Accordingly, the output of all 5-digit classes with similar end products must be combined before comparisons are made with import levels, because the import classifications do not make these differentiations.

Because employment data are available only on an industry basis, we must consider the commodity-to-industry mismatch when relating product-based measures of import penetration or export proportion to industry employment. Two available measures are useful in evaluating this problem. The first is the specialization ratio, defined as primary product output within the industry divided by total industry output (primary and secondary). The second measure, the coverage ratio, is the primary product output produced within an industry divided by total output of the primary product by all industries. If these two measures are fairly constant over time, then the industry-to-commodity mismatch should not present a major problem when changes in commodity-based import penetration or export proportion are compared with changes in industry-based measures, such as employment.

Data duplication. In computing measures of import penetration at the 4-digit SIC level, domestic product-based output must be aggregated and matched to imports. Aggregation of 5-digit product-class shipments to a 4-digit level will result in duplication to the extent that these commodities are used as materials in other commodities produced within the industry considered. (There are no similar problems of duplication in the import data, because only final products are recorded.) Most domestic output classes covering contract and commission work have been excluded to minimize duplication in the valuation of output. However, in lieu of an appropriate general measure of duplication, such as the percentage of output currently accounted for by intraindustry sales, it can only be noted that, if there is substantial duplication in the measurement of domestic output, the corresponding measure of import penetration will be understated.

Comparability of commodity classes. The available trade data are not ideal for the calculation of import penetration ratios or export proportions. Limitations include problems of valuation, timing, coverage, and comparability with classifications for domestic output.

Perhaps the most critical problem is the incongruity among classifications used for reporting domestic production, U.S. imports, and U.S. exports. Reported domestic production (as well as employment) is based on the classification of domestic economic activity of establishments according to the *Standard Industrial Classification* (SIC) *Manual*, 1972 edition. U.S. imports are reported on the basis of more than 10,000 legal tariff commodity classifications, designed for the collection of duties, in the *Tariff Schedules of the United States Annotated* (TSUSA). Finally, U.S. exports are reported on the basis of the Commerce Department's more than 4,000 Statistical Classifications of U.S. Exports (Schedule B).

The three classification structures (SIC, TSUSA, Schedule B) were designed for different uses. The SIC nomenclature is organized by stage of processing (for example, raw materials, manufactured products, services, and so forth). The origin of production is the establishment primarily responsible for output. In some cases, the method of manufacture or process, or market use, is important for industry classification. On the other hand, the trade classifications are commodity based; that is, they define objective commodity characteristics, material content, operating characteristics, and so forth, which may cross industry lines. In the case of imports, these commodity characteristics are important for the determination of any applicable duty.

For the purpose of relating imports (exports) to output, individual TSUSA (Schedule B) commodity numbers are assigned to a 5-digit SIC-based product class. In cases where the TSUSA (Schedule B) numbers include items which should be classified under two or more SIC-based output codes, an assignment is made to that code under which the principal content of the TSUSA (Schedule B) number appears to belong, if such an assignment will not significantly overcount the SIC classification to which the TSUSA (Schedule B) number is assigned or undercount the other SIC classifications to which it partially belongs. Where it appears that distortions will result from the assignment of an entire TSUSA (Schedule B) number to a single SIC-based output code, the principal SIC-based output classes are combined to form a more comprehensive SIC-based import (export) code, and the pertinent TSUSA (Schedule B) data are assigned to the combination. For the 1972 edition of the SIC, and its 1977 Supplement, there are 452 4-digit SIC-based manufacturing output codes and 347 (409) 4-digit SIC-based manufacturing import (export) codes. As one can see, the concordance between domestic output and either SIC-based imports or exports (and for that matter, even between SIC-based imports and exports) is not perfect.

Under Section 608 of the Trade Act of 1974, the Departments of Commerce and Treasury, along with the International Trade Commission, are working to improve the different classifications used for reporting domestic production, imports, and exports. Since the signing of the Act, significant improvements have been made. A completely new Schedule B classification for exports, structured after the TSUSA numbering scheme for imports, was introduced in 1978. In addition, new and more detailed TSUSA classifications are introduced each year, which in many cases permit better associations with domestic output classifications. But while these improvements in comparability are critical for relating trade to domestic economic activity, they present substantial problems for time-series analysis, because the improvements are often achieved at the cost of breaks in individual classification series. For example, only 318 of the 347 4-digit SIC-based import classifications currently available can be matched to output on a consistent basis for the years 1972–79.

In some cases, it is inappropriate (or impossible) to calculate a measure of import penetration, because comparable import data are not available for certain domestic output classifications (for example, morticians' goods, screw machine products, and so forth). In most cases this is not because these items are not imported, but because the different classification structures used for imports (TSUSA) and output (SIC) do not distinguish product characteristics on the same basis. In some cases, the tariff classifications are not defined precisely enough to permit association of import data with 5-digit detailed domestic output classifications. However, where it is likely that the domestic product class is subsumed in imports at the 4-digit level, it is included in the calculation of the import penetration measure. (For example, products like canned baby foods, SIC 20321, are assumed to be included in the broader import grouping for canned and preserved fruits and vegetables.)

The value of manufactures shipments at the 4-digit commodity level often includes a small amount which is not distributed among the individual 5-digit product classes. When SIC-based import groupings represent combinations of product classes from different 4-digit groups, a share of the undistributed output for the 4-digit output class is allocated to each output product class according to the 5-digit product-class share of the 4-digit total. Because this allocation is an approximation, the value of shipments for the 4-digit import commodity group might be slightly misstated.

Valuation. Differences in the method and point of valuation of imports and exports present major problems in comparisons with domestic output. Output shipments values are sample estimates, subject to error, and usually relate to the point of production. They include interplant transfers and are gross output measures (value added plus cost of materials).

In the above analysis, exports were valued at the point of exportation—seaport, borderpoint, or airport. The export value represents the selling price, or cost if not sold, and includes expenditures for freight, insurance, and other charges to the export point. In addition, the exporter's trade margin above cost boosts the export value in relation to producers' values. Information on the magnitude of this incremental margin is not available on a commodity-by-commodity basis. And, because export values pertain only to direct exports, and not to commodities which are incorporated into other, more finished products and exported in finished form, the relation of exports to shipments for intermediate products (such as steel shapes) is considerably understated.

Beginning in 1974, the Census Bureau began reporting imports on an f.a.s. basis (transaction value, f.o.b. port of exportation) and on a c.i.f. basis (value of the import at the first port of entry), in addition to the previously reported customs value. The customs value, which is used in this article, has been the basic valuation for duty-collection purposes since the inception of the tariff schedules. It usually represents the value in the foreign country and excludes duties, insurance, and other charges. Until recently, customs values did not necessarily represent transaction values. Certain products were valued for customs purposes on the basis of their American Selling Price (ASP), which in most cases was above the actual transaction value. However, under the Customs Valuation Code of the Trade Agreements Act of 1979, the ASP valuation practice is to be phased out and replaced with a transaction-based valuation. As a result, beginning with the compilation of 1982 trade statistics, the Census Bureau is substituting the transaction-based customs value for the f.a.s. value, and discontinuing the compilation of f.a.s. import values.

Of the three alternative import valuations, customs value, f.a.s., and c.i.f., the last would be preferred, because it would reflect the purchase price, freight, insurance, and other charges (except overland charges from Mexico or Canada). To obtain a landed value, customs duties assessed should also be added. This landed value would be the most appropriate measure to use in comparisons with domestic output. Because customs value was used in the above analysis, the import values understate the landed U.S. market value. However, the Census Bureau has tabulated SIC-based import penetration measures for 1974 using all three valuation bases, finding that in most cases there are no major differences, while in some there might be differences of as much as 2 percentage points.

Both imports and exports exclude low-valued shipments and mail entry items. To the extent these items are important in a product category, the valuation will be understated.

With few exceptions (for example, used tractors, cars, and tires), used or rebuilt commodities are classified in the same import or export group as new merchandise. Import penetration measures will be overstated to the extent that used or rebuilt products are significant in trade, because domestic shipments data usually do not include such commodities.

Differences in labor requirements for imported commodities present a major problem in value comparisons with domestic output when inferences are made about the employment associated with a particular commodity group. A commodity group should be defined with sufficient product detail to ensure homogeneity with regard to labor requirements. But in the foregoing analysis, imports are not differentiated by supplying country, a primary determinate of labor input and costs. Products are assumed to be homogeneous within world industrial sectors, and are distinguished only between those which are imported and those which are produced domestically. Imports are compared with like or similar domestically produced commodities on a dollar-for-dollar basis. While this method is probably more valid for the analysis of the balance of payments, it has severe limitations if such a one-to-one correspondence between output and imports is inferred. Different wage and cost structures in each country will affect current dollar value comparability between domestically produced and imported goods. Furthermore, any estimate of the U.S. labor requirements necessary to produce output equivalent to the imported amount would be affected by differences in the valuation of imports and output.

Productivity and people

A number of economic factors have created a new awareness of the human factor in the productivity equation: inflation, the high cost of money, slow economic growth, high energy costs, and increased foreign competition have all served to broaden our perspective. Although in the past top management has tended to downgrade or minimize the importance of the human factor, there is a new awareness of its significance today. A national opinion survey of leadership in the United States in 1979 revealed that government leaders considered improved employee relations to be one of the principal avenues of productivity improvement. Increasing awareness by the chief executive officers in American industry of this source of productivity will also focus corporate attention on more innovative programs within the workplace.

How valid are estimates of occupational illness?

While the annual BLS survey measures few chronic, long-latent, or fatal illnesses, estimates derived from other studies can prove statistically flawed and inaccurate

HARVEY J. HILASKI AND CHAO LING WANG

Incidence rates of occupational disease, published each year by the Bureau of Labor Statistics, understate the total impact of the work environment on workers' health.[1] This is so because the statistics virtually exclude chronic types of illnesses, as well as illnesses having a long latent period whose relationship to the job often surfaces only after retirement or death.

Alternative methods of measurement confirm that an undercount exists, but differ concerning its magnitude. This article examines some of the alternative methods of estimating occupational diseases and suggests that a consensus on the adequacy and reliability of the estimates is not likely.

One of the first studies to highlight the scope of occupational disease in this country was a pilot study sponsored by the National Institute for Occupational Safety and Health (NIOSH). Confined to cross-sectional samples of workers in designated small industries in Oregon and Washington, the study was designed to determine the usefulness of a set of medical procedures for diagnosing occupational disease, and to ascertain how much new data on occupational illnesses would be generated by this method. The results of the study, published in 1975, underscored the issue of a large undercount in current occupational illness statistics, primarily those of BLS.[2]

When analysts compared counts of cases of "probable occupational disease" from the pilot study with those from employer logs maintained under regulations of the Occupational Safety and Health Administration (OSHA), and with employer workers' compensation records, they found that nearly 90 percent of the cases (approximately 400) uncovered in the pilot study were not listed in employers' files.[3] In effect, the findings indicated that the procedures normally followed by employers in recording and reporting occupational illnesses in fulfillment of legal requirements result in a gross underestimate of occupational disease in the United States.

It should not be surprising that most of the "probable occupational disease" cases found in the pilot study were not included in employer records. Consider, for example, that of the 346 cases discovered in the study, hearing loss was most prominent, amounting to about 28 percent. This condition usually has a gradual onset, with the result that the worker may be unaware of any defect in hearing unless he or she undergoes a hearing test such as that administered in the study. Moreover, hearing loss is often part of the aging process; without baseline data and subsequent periodic testing of the work environment and resulting effects on the worker, the occupational relationship can be seriously challenged.[4]

The NIOSH study results may be questioned in several aspects, including possible bias inherent in the special procedures used to assess the health status of surveyed workers. However, the design is a feasible method for

dealing with the detection of occupational diseases which are not readily apparent. Unlike the BLS annual survey, which measures the incidence of occupational disease, or the number of new cases recognized by employers as occupational in keeping with regulatory criteria, the NIOSH study measured the prevalence of occupational illness, or the level of occupational illnesses existing at a given time. For some purposes, prevalence is the more meaningful measure, in that it reflects the universe of persons with disease whose medical and economic needs may warrant special attention. However, high prevalence does not necessarily indicate high risk; instead, it may reflect an increase in survival, perhaps due to improved medical care. Conversely, low prevalence may reflect either a rapidly fatal process or cure of disease. The incidence measure is better adapted to keep a "running tab" on the health effects of workplace hazards, except for that component of occupational disease which is chronic in nature or of long latency.

Indirect estimates

Other studies and reports on occupational health problems have also pointed to an undercount in current illness estimates, but they are largely based on indirect evidence. The lack of reliable measures of occupational illnesses nationally has necessitated use and manipulation of surrogate data from epidemiologic or other studies to produce rather specific estimates of occupational diseases. On the basis of such data, a 1979 Labor Department report to Congress claimed that a conservative estimate of the prevalence of byssinosis among nearly 560,000 workers exposed to cotton dust at current levels was 83,610.[5] In 1980, another congressional report by the Department (hereinafter referred to as the Interim Report) provided several estimates of respiratory disease prevalence or deaths from worker exposure to asbestos, silica, beryllium, cadmium, chromium, arsenic, nickel, coal tar products, and diisocyanates.[6] Among other things, the Interim Report stated that, of 1 million workers currently exposed to silica, an estimated 59,000 will develop "some level" of silicosis; it also predicted 43,230 lung impairments as a result of exposure to diisocyanates, chemicals used to produce plastic products.

Much like the NIOSH study results, these estimates suggest a substantial undercount in the regularly published national statistics, which for 1980 showed 2,200 cases of all "dust diseases of the lungs."[7] (The BLS survey does not ask employers to specify recognized occupational illnesses such as asbestosis, byssinosis, and silicosis and thus provides no direct estimates of the incidence of these diseases.) It seems worthwhile, therefore, to examine more closely the major methodologies and techniques commonly used in deriving indirect estimates of occupational disease.[8]

Prevalence of disease. Prevalence rates were used to derive the estimate for silicosis cited above. These rates express the proportion of the population having a disease at a given time, regardless of time of onset. But because epidemiological studies, the major source of prevalence estimates of occupational disease, are confined to a particular population with a specific exposure, extrapolation of the findings to other, larger populations requires caution. Table 1, excerpted from the Interim Report, will be used to illustrate some of the limitations in the use of prevalence rates for this purpose.

The exposed population figures, obtained from a variety of sources, including the Mine Safety and Health Administration and NIOSH, are not representative exclusively of the exposed work force. The more important figures in this table are the prevalence rates, which were obtained from various special studies. Estimates of the numbers of disease cases were calculated by multiplying the exposed populations by the prevalence rates.

The crucial problem in applying prevalence rates derived from special studies to an entire production work force is the lack of assurance that the composition and levels of exposure of the larger population are the same as those of the worker group studied. The group of workers selected for epidemiological study is usually not a statistical sample of all production workers in the industry; therefore, the prevalence rates from such a study cannot be generalized to the larger population.

Use of the specialized prevalence rates in deriving the silicosis estimates probably led to biased results. For example, the 10-percent prevalence rate for the granite industry, which was adapted from an article published in the *Archives of Environmental Health* in 1974,[9] was not a prevalence measure of silicosis or other respiratory disease, as would be expected. The source data related only to current dust exposures in the Vermont granite

Table 1. Estimated number of cases of silicosis among currently exposed workers

Industry	Population exposed	Prevalence per 100 persons	Estimated number of disease cases
Total	1,057,000		59,102
Mining:			
Metal	24,000	3.4	816
Coal	126,000	.5	630
Nonmetal	7,000	.8	56
Quarry:			
Granite			
Sand or gravel	4,000	10.0	400
	40,000	10.0	4,000
Stone, clay, and glass products ..	511,000	2.0 – 20.0	31,500
Foundries:			
Iron and steel ...	192,000	4.0 – 9.0	16,700
Nonferrous	75,000		
Abrasive blasting ..	78,000	6.5	5,000

sheds. But for estimating purposes, it was assumed that sand and gravel workers have the same "prevalence rate" as the granite workers, under further assumption of a similar degree and duration of exposure. In the case of the stone, clay, and glass products industry, a specific prevalence rate was selected for estimating purposes, although special studies showed a range of rates. While the chosen rate—6.16 percent—appears conservative, there is no reason to assume that it is a better estimate than any other within the wide 2- to 20-percent range of individual study results. If prevalence rates had been calculated from sample data, the precision of the estimates could be measured by standard errors. But for the data in table 1, the standard error of estimated prevalence is not available, and the precision of the estimates is therefore not known.

Dose-response. Dose-response studies generally attempt to establish a statistical relationship between dose (exposure) and response (onset of disease or death). For simplicity, this will be illustrated by example. Eight of 22 North Carolina textile manufacturing plants were selected for a 1970–71 study of cotton textile workers.[10] A dose-response curve was fitted to the resulting data on the prevalence of byssinosis among a group of 1,259 workers in the cotton preparation and yarn area. (See table 2.) From the fitted curve, the byssinosis prevalence rates and their 95-percent confidence limits for workers in the cotton preparation and yarn area were predicted at various cotton dust levels of exposure:

Dust level (mg/m^3)	0.1	0.2	0.5
Predicted prevalence per 100 workers	6.5	12.7	25.8
95-percent confidence interval	5.0–8.5	10.8–14.9	22.5–29.3

The referenced study suggested that a reasonably safe level of lint-free cotton dust is 0.1 mg/m^3 in the cotton preparation and yarn area, because nearly 94 percent of the workers exposed at this level had no symptoms of byssinosis.

As indicated in table 3, the authors of the Interim Report used the results of the North Carolina study to calculate the total number of expected byssinosis cases by multiplying 1977 BLS data for production workers in six yarn manufacturing industries by the prevalence rate of 25.8 per 100 workers—the prevalence predicted by the textile worker study for dust level exposure of 0.5 mg/m^3. But it is unrealistic to assume that all workers in yarn industries generally are exposed to such high levels of cotton dust. This assumption might not even be true of cotton preparation and yarn workers nationwide, the types of workers among whom the prevalence study was done. Even if it were, however, the results of this special study should not be construed as necessarily representative of production workers in all yarn manufacturing industries, because the occupational composition of other industry segments would probably not be similar to that of the cotton preparation and yarn area.

Table 2. Data on byssinosis prevalence by median dust level

Item	Median dust level (mg/m^3 rounded)									
	.06	.07	.10	.15	.23	.34	.51	.77	1.2	1.7
Sample size (n)	145	71	193	279	78	208	147	65	31	42
Cases of byssinosis (r)	5	2	14	27	10	39	37	30	14	17
Prevalence (r/n × 100)	3.4	2.8	7.3	9.7	12.8	18.8	25.2	46.2	45.2	40.5

Closer scrutiny of the dose-response relationship in the cotton preparation and yarn area makes the selection of the 25.8 prevalence rate even more puzzling, as only about 285, or 23 percent, of the 1,259 workers fell in the categories exposed to median dust levels 0.5 mg/m^3 or above. According to the data in table 2, the average overall byssinosis prevalence for the entire study was 15.5 per 100 workers, or 195 persons.

For the study of illnesses such as byssinosis, information on duration or years of exposure to the hazard is also crucial. This factor should be taken into account because a worker with 10 or 20 years of work exposure would seem to be more susceptible to byssinosis than a worker with a few years of exposure. Moreover, a worker's exposure level may change over the years, due to changes (not always for the worse) in working conditions, including ventilation, industrial hygiene practices, and so forth. In short, a worker normally experiences different amounts of exposure, of varied duration, over the course of his or her employment. If the dose-response relationship curve is not adjusted for the extent of exposure, its accuracy is diminished. Unfortunately, comprehensive data on the intensity, duration, and fluctuation of exposure are rarely available, particularly in retrospective studies of the type used in making the above estimates.

In general, dose-response relationship curves are nonlinear, monotonic (increasing or decreasing), and have lower and upper asymptotes (usually, but not always, 0 and 100 percent). The models tend to operate well in a restricted range of exposure or dosage levels, but not over the entire range; that is, they may be useful in determining the "safe" level of exposure, but they are not suitable for developing national or industry-wide statistics on occupational illnesses.

Standardized mortality ratio. The standardized mortality ratio has been widely used as a summary index of mortality in occupational epidemiologic studies. The ratio is a method commonly used to accomplish indirect age adjustment by applying age-specific death rates of a standard population to a study population to yield a

Table 3. Expected numbers of byssinosis cases, selected yarn manufacturing industries

Yarn manufacturing	Standard Industrial Classification Code	Exposed workers	Assumed prevalence (in percent)	Expected cases
Broad woven fabric mills, cotton	2211	86,600	25.8	22,340
Circular knit fabric mills	2257	1,000	25.8	300
Yarn spinning mills	2281	34,400	25.8	8,880
Texturizing, throwing, twisting, and winding mills	2282	13,900	25.8	3,590
Thread mills	2284	3,600	25.8	930
Tire cord and fabric	2296	1,600	25.8	410

Source: U.S. Department of Labor, *An Interim Report to Congress on Occupational Diseases*, June 1980, table A-1, p. 126.

number of "expected" deaths. It is defined as:

$$\text{SMR} = \frac{\text{total observed deaths in a study population}}{\text{total expected deaths in the population}}$$

A ratio greater than 1 means that more deaths have been observed in the study group than would be expected on the basis of rates for the standard population; conversely, fewer deaths than expected are indicated by a ratio less than 1. A test, such as chi-square, is generally used for determining the level of significance of the results.

If the focus is on mortality from hazards in the workplace, an ideal standard population would include all workers in the Nation. But because mortality data are not available in this detail, the total U.S. population, or the male population, is generally selected as the standard. Consequently, misunderstanding sometimes arises in applying standardized mortality ratios to estimate the total number of deaths caused by certain diseases in industry.

In the Interim Report, the ratio was used to derive estimates of work-related lung cancers.[11] Data from three sources were used in the computations:

(1) The number of workers exposed to beryllium compounds and oxides in end-user processes, estimated at 50,000, was obtained from the NIOSH 1972 National Occupational Hazard Survey.

(2) The mortality ratio of 1.6 for lung cancer among beryllium workers was taken from epidemiologic studies.

(3) The 1976 U.S. age-adjusted incidence for lung cancer of 116 per 100,000 males over age 20 was used.

The number of expected deaths from lung cancer among workers in end-user industry processes was then calculated as: 50,000 × 1.6 × (116/100,000), or about 93 lung cancer deaths. Is this a valid estimate of all lung cancer deaths in this industrial population which were due to exposure to beryllium compounds?

First, it is important to understand that a standardized mortality ratio of 1.6 does not mean that the mortality rate of the study population is 1.6 times that of the standard population and can thus be used as a multiplying factor to obtain the number of deaths in a broader population. Even when exposed to the same health hazards and having the same age-specific death rates for all age groups, different study populations will yield different values of the standardized mortality ratio if their age distributions differ. Obviously, then, the ratios should not be used in estimating the number of deaths due to disease in populations which differ in composition from a study population.

Second, a high ratio does not imply that all deaths from lung cancers, for example, are caused by occupational exposure; it tells us only that the study population has an unusually high mortality risk. We do not know what percentage of deaths actually resulted from exposure, in this case to beryllium. Even if the standardized mortality ratio were interpreted to mean that the number of deaths of the study population is 1.6 times that of the standard population, 58 (that is, 93/1.6) deaths per year from lung cancer would have occurred in the study population irrespective of any exposure to beryllium. That leaves 35 deaths per year (or about 38 percent of total estimated deaths) which might be attributed to, or aggravated by, exposure to beryllium compounds. At most, the estimate of 93 deaths depicts the total cancer toll among the occupational group, not the excess cancer resulting from beryllium exposure.

Relative risk. Because incidence or other direct measures of occupational disease are generally lacking, epidemiologic study of occupational morbidity often relies on a measure of excess risk of a disease among workers in specified working environments to determine the association between certain occupational factors and the incidence of disease. One such measure is relative risk.

As we will see, relative risk also is subject to misuse in making estimates of occupational disease in industry, perhaps because of confusion about its definition. This can be illustrated again by an example from the Interim Report. From the National Occupational Hazard Survey, 98,090 workers were estimated to be exposed to chromates in chromate pigment production and, as noted, the 1976 U.S. male age-adjusted incidence rate of lung cancer for those over age 20 was 116 per 100,000. Based on these two figures and a chosen relative risk of 5, the estimated number of lung cancers per year among the 98,090 workers was 570 cases: (exposed population) × (incidence rate of male population) × (relative risk) = (98,090) × (116/100,000) × 5 = 570 cases.

The report stated: "Based on three studies reporting relative risks from 2.3 to 38, a relative risk of 5 will be used for workers exposed to chromate compounds. . . ."[12]

Seemingly, this is a conservative choice, but in reality there is no way to tell whether the relative risk of 5 is appropriate or not, because we have no information on its precision. More basic issues are whether relative risk should even be used to estimate the incidence of lung cancer cases, *and* what is involved if one does so.

Relative risk is a measure of the strength of the association of the disease with a certain factor, such as exposure to a specific chemical, and thus is an important statistical tool in retrospective epidemiological studies. It is defined as the ratio of the incidence rate of those exposed to a factor to that of those not exposed. Conversely, relative risk can be used to compare groups of subjects diagnosed as having a disease to determine if the groups differ in the proportion of persons who had been exposed to the specific factor or factors. However, because retrospective study entails looking at the historical frequency of the suspected cause in a diseased group and a control group, the incidence rates of the diseased among the exposed and unexposed cannot be estimated directly but only approximated by relative risk, an odds ratio (or risk ratio).

Consider the following tabulation, in which the total T_i of the ith group of workers in a study population T ($T = \sum_{i=1}^{K} T_i$), where K equals the total number of groups, is divided as:

	With disease	*Without disease*	*Total*
Exposed to factor	A_i	B_i	$A_i + B_i$
Not exposed to factor .	C_i	D_i	$C_i + D_i$
Total	$A_i + C_i$	$B_i + D_i$	T_i

Data classified in the table may be obtained from prospective, cross-sectional, or retrospective studies. According to the tabulation above, the proportion of workers exposed to a factor and having the disease is $A_i/(A_i + B_i)$, while the corresponding proportion of unexposed workers with the disease is $C_i/(C_i + D_i)$. Thus, the relative risk of disease for exposed workers is: $A_i(C_i + D_i)/C_i(A_i + B_i)$. But because the incidence of a specific disease in a population tends to be low, the calculation $(A_iD_i)/(B_iC_i)$—that is, $(A_i/B_i)/(C_i/D_i)$—provides a close approximation of the relative risk (but not of the incidence of disease) for the ith group of individuals. For an overall relative risk, a commonly used formula is:[13]

$$R = \sum_{i=1}^{K} (A_iD_i/T_i) \;/\; \sum_{i=1}^{K} (B_iC_i/T_i)$$

Because age is an important factor affecting incidence of disease, it should be accounted for in measurements of overall relative risk. In such an age-adjusted risk ratio, T_i is the total of the ith age group. The chi-square test is commonly used to determine whether the relative risk is significantly different from 1. Using a risk ratio from a particular study and an incidence rate for the general male population to estimate the extent of occupational disease in a larger population exposed to a specific factor assumes similarity among the age and sex distributions of all groups. However, in the Interim Report's estimate of disease from exposure to chromate compounds, the composition of the general male population and the exposed population may not be similar to that of any special study population. Therefore, use of the relative risk of 5, selected from a range, may produce biased results.

In brief, relative risk is a measure only of the strength of the association between the disease and the exposure factor. If significantly different from 1, it indicates only that the disease is strongly associated with the exposure factor, not that the factor necessarily causes the disease. Any firmer conclusion would require further study. Relative risk is surely a critical measure for assessing the etiologic role of a factor in disease, but it is not suitable for estimating the incidence of disease.

Cancer related to occupational factors

What fraction of cancer incidence in this country is attributed to occupational exposure to carcinogens in the workplace? An unpublished 1978 report prepared jointly by several research institutes indicated that about 20 percent of all cancers are occupationally related and stated: "If recent evidence is considered and if the full consequences of occupational exposures in the present and recent past are taken into account, estimates of at least 20 percent . . . may even be conservative."[14] The report concluded that earlier estimates that only 1 to 5 percent of all cancers in the United States were attributable to occupational factors had not been scientifically documented and that Dr. Philip Cole's 1977 estimates of less than 15 percent for men, and less than 5 percent for women, contained a large element of uncertainty.[15] The results from the joint report have been cited in numerous publications, and questions have been raised concerning their validity.

The 20-percent overall estimate resulted from a two-step merger of the results of several separate studies. The first step developed estimates of the fraction of cancers due to asbestos exposure, while the second compared the risks from asbestos exposure with those from five other high-exposure substances, with the final result based on that comparison. Details of the estimation procedure follow.

According to the report, about 8 to 10 million workers have been exposed to asbestos since the beginning of World War II, and approximately 4 million have had heavy exposure. On the basis of a longitudinal study of a cohort of insulation and shipyard workers, the report indicated that, of deaths of heavily exposed workers, 20 to 25 percent were from lung cancer, 7 to 10 percent from pleural or peritoneal mesothelioma, and 8 to 9 percent from gastrointestinal cancer. Summed up, this suggests that 35 to 44 percent of cohort deaths were attributable to cancer diseases. Accordingly, the joint study group concluded that, over the next 30 years, at least 1.6 million (about 40 percent of the 4 million) heavily exposed workers would die from the asbestos-related cancers listed above. Based on an assumption suggested by data from a second source, the excess risk to the remaining less heavily exposed workers (4 to 7 million) was estimated to be one-fourth of that for the heavily exposed (a 10-percent risk, obtained as ¼ × 40 percent), yielding a cancer estimate for this group of 0.4 to 0.7 million. This raises the total to between 2.0 and 2.3 million cancer deaths over the next three decades, with expected averages of 58,000 to 75,000 cancer deaths per year associated with asbestos alone. The joint study indicated that this excess number of cancer deaths would account for roughly 13 to 18 percent of all expected cancer deaths.

In the second step, the study presented data on carcinogenic risks to workers found to be exposed to five substances in addition to asbestos during a 1972–74 National Occupational Hazard Survey.[16] Table 4, adapted from the study, shows selected results. The risk ratios were either standard mortality ratios or risk ratios selected from a range of values obtained from other epidemiological studies. The report indicated that the figures were not precise estimates, but reasonable ones for comparison purposes, because they were all derived by the same method.

Other conclusions pertaining to the second step of the joint study:

- Excess cases for the other five substances combined are about 33,000 cancers per year, versus 13,900 for asbestos alone (table 4). The data show that these five agents together pose hazards similar to or greater than those posed by asbestos.
- The projected numbers of excess cancers are only for the 1972–74 groups of N-size workers. But because of workplace turnover, the actual number of workers exposed over time will be several times larger than N.
- Consequently, the excess number of cases from asbestos (13,900) among the 1972–74 group underestimates the annual expected number of cancer deaths related to asbestos—58,000 to 75,000, as derived in step 1—by a factor of 4 to 5.
- Because the data for the five other substances listed in table 4 were derived in the same way as those for asbestos, the estimates may likewise underestimate the number of cancers attributable to these substances.

Table 4. Risks of disease associated with exposure to selected substances

Chemical substance	Estimated number of workers exposed, 1972–74 (N) (in millions)	Diseases of risk	Risk ratio (R) (assumed)	Age-adjusted incidence of disease (I) (per 100,000)	Projected number of excess cases (R-1)IN
Asbestos . .	1.6	Lung cancer	6.6	116	10,400
		Mesothelioma	(one third	of lung cancer)	3,500
Arsenic . . .	1.5	Respiratory cancer	4.7	131	7,300
Benzene . . .	2.0	Leukemia	5	17.9	1,400
Chromium .	1.5	Respiratory cancer	5	131	7,900
Nickel	1.4	Respiratory cancer	5	131	7,300
Petroleum products .	3.9	Lung cancer	3	116	9,100

SOURCE: National Cancer Institute, National Institute of Environmental Health Services, National Institute for Occupational Safety and Health, *Estimates of the Fraction of Cancer in the United States Related to Occupational Factors*, September 1978, (unpublished), table 2, p. 33–38.

- According to results from the first study step, asbestos alone will account for between 13 and 18 percent of all cancer deaths over the next 30 years. The data for the five other substances suggest at least 10 to 20 percent additional cancer deaths. Hence the study conclusion that occupationally related cancers may make up 20 percent or more of cancer deaths in forthcoming decades.

Closer examination of the joint study findings indicates that they may not be fully supported by data from the various studies used in their development, a conclusion corroborated in a report prepared for the Office of Technology Assessment, U.S. Congress.[17]

First, a study of causes of nearly 2,300 deaths among a cohort of 17,800 asbestos insulation workers contributed the finding that 35 to 44 percent of workers heavily exposed to asbestos died of cancer. The joint study group selected 40 percent as an approximation of the cohort's fatal cancer risk, and applied this percentage to a national population of 4 million workers considered to be heavily exposed to asbestos. This extrapolation was based on the unstated and probably unjustified assumption that the cohort of asbestos insulation workers was representative of the worker population of mixed industries. The mixed industry population might well differ from the cohort group not only in levels and length of asbestos exposure, but also in terms of population factors, such as age, sex, race, and percentage of smokers, which play significant roles in risk assessment. From the statistical point of view, application of the results from a study population to other populations of different composition and exposure experience usually produces biased estimates. The assumption that the risk of cancers for the less heavily exposed group of 4 to 7 million workers is one-fourth that of the heavily exposed group is similarly questionable. Consequently, the resulting total estimate of 58,000 to 75,000 asbestos-related cancer deaths per year is highly suspect.

Second, the analytic results by "causes" of death in the cohort group of asbestos insulation workers showed only the percentage distribution by disease, irrespective of cause; they did not indicate what fraction of cancer was induced or aggravated by asbestos alone or by any other specific exposure. Although it may be highly abnormal to find 20 to 25 percent of lung cancers and 8 to 9 percent of gastrointestinal cancers as causes of death among a group of workers, the actual percentage of cohort-group deaths specifically associated with exposure to asbestos remains uncertain.

Third, the method of estimating excess cancer cases or deaths for each exposure substance shown in table 4 may result in either overestimates or underestimates. Risk ratios do not in themselves provide the magnitude of risk, because they are greatly affected by the composition of the study population. In that the risk ratio is a ratio of observed to expected disease cases or deaths, any small increase in observed cases will greatly increase the risk ratio if the expected number of cases is small. This is especially true when the study population is small. Assume, for example, that study results indicate that 1,400 deaths were observed when only 1,000 were expected, yielding a risk ratio of 1.4. The chi-square value for the level of significance will be: $X^2 = (\text{observed-expected})^2/\text{expected} = 160$. To achieve the same level of significance for an expected number of 10, the observed number would have to be 50, and the resulting risk ratio would be 5. Thus, a small study population has a better chance to yield a large risk ratio than a large study population, if both experience the same hazards and have the same population composition. It is not surprising, therefore, to find that risk ratios vary widely among epidemiologic studies of workers exposed to the same chemical substance. It is more important to know whether the value of the risk ratio is significantly different from 1, which indicates that the risks for the exposed and nonexposed groups are not identical, than to determine the absolute magnitude of the ratio itself.

Fourth, the joint report considered 13,900 excess cases per year due to asbestos exposure to be underestimated by a factor of 4 to 5 under the assumption of high turnover of the work force. Because the report had already estimated 58,000 to 75,000 asbestos-related deaths per year in an exposed population estimated at 8 to 11 million, further inflation by this factor results in an incredible number of occupational cancers. Based on the age-adjusted incidence shown in table 4, the number of expected lung cancer deaths, excluding mesothelioma, among a 1.6 million male population over age 20 would be 11.6 million × (116/100,000) or 1,856, in the absence of any exposure to asbestos. It follows, then, that excess lung cancer deaths due to asbestos exposure alone (10,400) amount to 85 percent of all lung cancer deaths in this 1.6 million exposed population—that is, 10,400/(1,856 + 10,400). Add to this calculation the mesothelioma cases, and the figure becomes 88 percent, a rather astounding share considering all other cancer causes.

Estimates of the excess number of predominantly respiratory type cancer cases due to the five other substances for the given groups of exposed workers also are indicated in table 4. For these groups, the expected numbers of cancer cases in the absence of exposure would be: 1,970 (arsenic), 360 (benzene), 1,970 (chromium), 1,830 (nickel), and 4,520 (petroleum products), by direct application of the corresponding incidence rate. This means that the proportion of total cancer cases associated with each of these five chemicals would amount to 79 percent, 80 percent, 90 percent, 80 percent, and 67 percent, respectively. These proportions appear unreasonably high.

Finally, the joint study group considered the excess number of cancers attributed to the five other substances to be underestimated also, based on the two-step findings for asbestos and applying the same logic. However, this inference is not justifiable, because estimates for the other substances were obtained independently, and the magnitudes of the estimates were greatly affected by the value of the risk ratio chosen for each.

Disability-impairment data

Three types of disability data are available to the occupational health analyst: Social Security Administration data from the various surveys of disabled adults; the Social Security Administration's disability applicant files; and the National Center for Health Statistics' Health Interview Survey data. These data sets also suggest that there are greater numbers of health problems with some occupational connection than published data from employer-based surveys would indicate, but they do not necessarily establish a causal connection between work and disease. Therefore, it may be beneficial to discuss briefly the conceptual framework of these data bases.

The disability study. This study was an analysis of disability data obtained from an interview survey of 18,000 persons age 20 to 64, who had been selected from the 1970 5-percent census sample.[18] The survey was conducted by the Bureau of the Census for the Social Security Administration. Of the 18,000-member sample, 11,700 had been selected from among those persons who had a disability prior to October 1969 as indicated on the 1970 census questionnaire. A mail screening in 1971 resulted in selection of another 1,200 recent onset cases and 5,100 nondisabled persons. Disability in the study was defined "severe," if it precluded work altogether, or "partial," if it limited the kind or amount of work performed.

Based on survey results, it was estimated that about 15 million persons age 20 to 64 nationwide were disabled from all causes. To determine the job-relatedness of a disability, the survey respondent was asked: "Was your (main condition or illness) caused by your job?" Of the resulting estimated 2.4 million job-caused disabilities, 1.7 million were attributed by the author of the study to occupational disease. (For purposes of the study, occupational diseases were defined as all cases of disability which were not caused by an accident on the job.) The study further stated: "Because of limited understanding of what diseases are occupational in nature, it is likely that the actual number of occupational disease cases is much higher" (page IV).

The study indicated that, of the 1.7 million persons disabled by occupational disease, 1.1 million or two-thirds were partially disabled. Among the 0.6 million severely disabled, musculoskeletal and cardiovascular conditions accounted for almost 60 percent of all conditions reported. About 25 percent had mental and digestive ailments and 9 percent, respiratory conditions. Cancer caused by occupation was estimated among the severely disabled at little more than 1 percent, slightly over 6,000 cases.

Can we say that these are good estimates? As the author of the study points out, the survey provided a snapshot of the population at a given time.[19] Thus, the resulting estimates measured the prevalence of occupational disease, counting as they did all existing disabilities without regard to time of onset or diagnosis. The occupational relationship was subjectively perceived by respondents and may or may not have been corroborated by objective medical evidence. Except perhaps for the musculoskeletal impairments, the other conditions were of a type for which objective evidence of occupational causality might have been difficult to obtain.

Finally, while national estimates based on survey data of self-perceived work-related disabilities suggest that an undercount in employer-based occupational illness estimates does exist and in some identifiable parameter, it appears that those diseases which have long latent periods and have yet to be diagnosed are missed in this approach as well. Many long-latent diseases or aggravating disease symptoms of possible occupational origin are recognized beyond the cutoff age of most direct surveys. When disease appears after a worker has lived at least a normal life span, other factors, related to the aging process, enter which may lessen the urgency to determine precise causes.

Disability applicant files. The Social Security disability program provides benefits to disabled adults with work experience in employments covered by the Social Security Act, and to adults disabled since childhood who are dependents of disabled or retired work beneficiaries or of deceased insured workers. To qualify, claimants for Social Security Disability Insurance must prove that they are both disabled and unable to engage in any substantially gainful work due to their medical condition. Two sample data files from disability applicant records are maintained by the Social Security Administration (SSA), the Continuous Disability History Sample (CDHS) and the Longitudinal Sample of Disability Insurance Applicants (LSDIA). CDHS contains about 25 percent of allowed claims and 10 percent of denied claims, while LSDIA is a 5-percent longitudinal sample of disability applicants.

Disability applicant records contain demographic information, such as sex, race, date of birth, education, occupation, and industry of employment, as well as important medical information, such as diagnosis (primary, secondary, and tertiary), listings of impairments, principal body system involved, and severity and duration of impairment. It is important to note, however, that in the recording and coding of disability cases, work-related illnesses are not distinguished from nonwork-related ones. That is, for adjudicative purposes, an occupational relation to the disease or disability does not have to be established. (Although occupations are associated with worker claimants, no causal relationship is required or intended.) According to a 1974 report by the U.S. Department of Health, Education, and Welfare, the leading causes of disability by diagnosis were listed as chronic ischemic heart, schizophrenia, osteoarthritis, emphysema, displacement of intervertebral disc, diabetes mellitus, rheumatoid arthritis, acute cerebrovascular disease, malignant neoplasm of trachea and lung, neuroses, pulmonary tuberculosis, and mental disorders.[20] This listing also contains types of diseases for which, obviously, objective evidence of occupational causation would be hard to come by.

To qualify for disability insurance, a claimant must have a health condition sufficiently incapacitating to be unable to engage in any substantial, gainful work. Thus, a worker may have an occupational disease, but be disallowed disability benefits because pursuit of gainful employment is still possible. Therefore, disability estimates based on SSA records are not precise and comprehensive indicators of occupational impact. In addition, the occupational history of an applicant is limited to his or her longest full-time occupation in the 10-year period preceding the alleged date of onset. Because a job-caused disability, especially one of a chronic nature, may have been due to an earlier exposure, and perhaps, to a different job, there is a potential bias in the use of these statistics for epidemiological study. While the SSA disability files are an important source of data for development of morbidity ratios which identify disease and occupational relationships worthy of further study, they are not suitable for deriving estimates of occupational disease.[21]

Health Interview Survey data. The Health Interview Survey of the National Center for Health Statistics is a nationwide survey of approximately 40,000 households, conducted on a continuous basis. It is designed to gather information on personal and demographic characteristics, illnesses, injuries, impairments, chronic conditions, and other health topics. Respondents are asked whether they worked in the 2 weeks prior to the interview week, and in what occupation and industry. Each year's sample includes about 120,000 persons, of whom roughly 50 percent are employed.

As data are processed and tabulated, the center publishes analytical reports on various topics. While very few reports have been published on the work force population as the primary study target, data files are available for research purposes. Like the Social Security Administration disability applicant data the center's data can serve important epidemiological research objectives, but should not be used to derive precise estimates of occupational disease incidence.[22]

DESPITE THEIR SHORTCOMINGS, the results of the studies and applied methodologies discussed above do, in combination, point to a larger impact of the workplace on the health of workers than is borne out in regularly published statistics, although the magnitude of the understatement remains uncertain. Continued efforts towards improved or new methods are needed to produce national estimates of greater credibility for the chronic and long latent disease component of job origin. Such efforts might include improved techniques for diagnosing occupational diseases; more sophisticated and efficient means of monitoring workers' health; education and training of doctors and workers regarding health hazards on the job; conduct of epidemiological studies representative of national experience; and establishing methodology for determining the contribution of job exposure to the origin and course of disease. ☐

Disability benefits for employees in private pension plans

Although benefits vary,
for many 20-year employees aged 55,
a private pension and social security
would replace about one-half of
the worker's pre-disability earnings

DONALD BELL AND WILLIAM WIATROWSKI

Although private pension plans are thought of primarily as a source of cash income for the elderly, they typically serve other functions as well. For example, they usually contain early retirement features and often provide pensions to workers who lose their jobs because of disability.

The high proportion of pension plans with disability retirement features is dramatized in data from the Bureau of Labor Statistics' annual survey of the incidence and characteristics of employee benefit plans in medium and large establishments.[1] Of the 1,002 private pension plans found in the 1980 survey, 86 percent had disability retirement features.[2] This article analyzes the various eligibility requirements for disability retirement and typical benefit levels, as found in these plans.

Disabled workers may have other protection as well. They often are eligible for social security benefits and also may be covered by private long-term disability insurance plans. This study includes retirement benefits and related long-term disability and social security benefits. However, excluded from the study are separate long-term disability plans which would be the only source of private disability income, and general early retirement provisions without specific disability features.

Two-thirds of the 861 pension plans with disability provisions offered immediate disability benefits. The remaining third deferred benefits until the employee reached the early or normal retirement age stipulated by the plan. However, immediate long-term disability insurance benefits were typically available to employees under deferred disability retirement plans. (Long-term disability benefits were less common when immediate disability pensions were paid.) Such private benefits are provided in addition to payments under the social security system when a worker is incapacitated.

Under retirement plans providing immediate disability pensions, benefits were available to workers meeting plan definitions of disability; commonly, service or age requirements, or both, were specified as well. Employees covered by deferred-benefit plans also had to reach the stipulated early or normal retirement age to receive benefits.

Illustrative benefit levels from all potential sources—disability retirement, long-term disability insurance, and social security—were calculated as a percent of pre-retirement earnings for a hypothetical worker disabled at age 55, with 20 years of service. Under these conditions, combined private pension and social security benefits tended to replace about half of pre-disability earnings in instances when private pension plans provided immediate retirement benefits. Replacement rates in many cases were more liberal where retirement packages furnished deferred pensions integrated with long-term disability benefits. As a rule, social security, rather than private plans, was the larger income source for the disabled worker.

Immediate and deferred benefits

Sixty-eight percent of the 861 disability retirement plans examined offered immediate pensions. The balance (32 percent) deferred benefit payments until the normal

---

Donald Bell and William Wiatrowski are economists in the Division of Occupational Pay and Employee Benefit Levels, Bureau of Labor Statistics.

retirement age or in some instances, at the employee's option, until the early retirement age.

A key element in any pension plan is the formula included for calculating benefits. (Common formulas involve percentages of an employee's career or terminal earnings and dollar amounts per year for which an individual is covered by the plan.[3]) Most of the pension plans studied used the same basic formula to calculate disability and normal retirement benefits.

Immediate disability retirement. Of the 583 plans with immediate disability retirement provisions, nearly three-fourths used an unreduced normal benefit formula for disabled workers. (See table 1.) That is, beneficiaries received pensions calculated as if disability occurred at the normal retirement age;[4] no reduction in benefits was made solely because of the early retirement age. Nevertheless, these disability pensions tended to be lower than those for normal retirement because benefits typically were based on shorter service.

An additional 15 percent of plans with immediate disability benefits reduced pensions because of the relatively young age of those who retire on disability. Nearly half of these plans provided for actuarial reductions; pensions for retirement at age 55 usually were about 61 percent below those for normal retirement at age 65 with the same service. The remainder of these plans provided for less than actuarial reductions, the average benefit for disability at age 55 being approximately 43 percent less than that for normal retirement at age 65.

The remaining 14 percent of the plans with immediate disability pensions based benefits on formulas designed to temper reductions caused by shortness of service or to yield higher returns than under the normal retirement formula.

Generally, plans do not provide for later modification of the benefits determined at the time of disability retirement. However, 7 percent of the immediate disability retirement plans specified a recalculation of benefits at age 65, mainly either to increase compensation for persons whose benefits were reduced because their disability occurred before normal retirement age or to raise benefits for those with short service at the time of disability retirement. Four percent recalculated benefits at age 65 based on the normal retirement formula and service at the date of disability; 3 percent recalculated on the basis of credited service at the time of disability plus the period of disability.

Deferred disability retirement. In sharp contrast to the typical practice under plans providing immediate benefits, only 16 percent of the deferred disability retirement plans based benefits solely on service at the time of disability. (See table 2.) Benefit calculations under most of the deferred plans granted service credit for all or part of the period between disability and the initiation of pension payments. Thus, 77 percent of these plans allowed service credit to accrue during all of the deferral period, while 7 percent allowed partial credit, usually for 1 or 2 years.

Table 1. Pension plans with immediate disability retirement provisions by type of benefit formula, medium and large establishments, 1980

Benefit formula	Plans with immediate disability retirement	Percent of: Plans with immediate disability retirement	Percent of: All disability retirement plans
Total	583	100	68
Unreduced normal benefits	418	72	49
Reduced normal benefits	85	15	10
Actuarially reduced formulas	39	7	5
Same as early retirement	29	5	3
Percent per year reduction between retirement and specified age	17	3	2
Other than normal benefits	80	14	9
Flat amount formulas	19	3	2
Dollars times years of service	24	4	3
Percent of unreduced benefit minus social security	20	3	2
Percent of earnings minus social security	12	2	1
Percent of earnings in highest of last years worked	5	1	1

NOTE: Because of rounding, sums of individual items may not equal totals.

Coordination of pensions and social security. Benefits under private pension plans may be coordinated with those under the social security system. This occurs through either offset or integration provisions in the private plans. Under the former approach, private benefits are reduced by all or part of the social security payment. Integration provisions apply separate benefit formulas to earnings above and below the social security taxable wage base; for example, 1 percent of earnings up to the social security tax base and 1.5 percent of earnings above that tax base for each year of service. Thirty percent of all pension plan participants in the 1980 study were covered by offset provisions; 16 percent were in plans with integrated formulas for normal retirement benefits.[5] Such coordination typically was applicable to disability retirement, too.

Long-term disability insurance

A review of disability benefits must also consider long-term disability insurance, which often supplements or serves as an alternative to disability pensions. Generally, these payments begin after sick leave and accident and sickness insurance are exhausted and continue as long as a disabled employee remains incapacitated, or until retirement age is reached. Forty percent of persons covered by the Bureau's 1980 survey of employee benefit plans participated in long-term disability plans. Specified benefits, including payments from social security and other government programs such as workers' compensation, were usually a fixed percent of monthly earnings. Almost two-thirds of the participants were in plans designed to provide 50 to 60 percent of pre-disability earnings; however, resulting dollar benefits were often limited by maximum coverage restrictions so that persons with high earnings may receive a lower percent of earnings for disability benefits.[6]

As expected, long-term disability insurance plans were more prevalent where retirement pension plans provided deferred disability benefits. Table 2 shows that 89 percent of deferred plans were in establishments with long-term disability plans financed either solely by the employer or jointly by the employer and employees. Nine percent of the deferred disability retirement plans were in establishments providing an optional long-term disability plan paid for entirely by the employees. Thus, only 2 percent have workers who cannot receive immediately available disability benefits from private sources related to their employment.

Long-term disability insurance plans were less prevalent when pension plans provided immediate disability retirement benefits. Twenty-seven percent of these pension programs were tied in with the insurance plans.

Coordination of long-term disability benefits with disability pensions and social security was almost universal. The most common method of coordination was by offset; long-term disability benefits were reduced by the amount of private pension and social security a disabled worker received. The total benefit received by an employee covered by such a program was the amount specified by the long-term disability plan, generally 50 to 60 percent of pre-retirement earnings. Offset provisions were in four-fifths of the long-term disability plans in establishments with either immediate or deferred disability retirement benefits. Substantially all of the remainder specified an overall maximum benefit from all sources, most often 70 or 75 percent of pre-retirement earnings.

Table 2. Pension plans with deferred disability retirement provisions by service credited and integration with long-term disability insurance, medium and large establishments, 1980

Characteristic	Plans with deferred disability retirement	Percent of: Plans with deferred disability retirement	Percent of: All disability retirement plans
Service credited:			
Total	278	100	32
Service when disabled	44	16	5
Service plus credit to normal or early retirement	215	77	25
Service plus partial credits	19	7	2
Integration with long-term disability insurance:			
Total	278	100	32
Insurance paid by employer or jointly by employer and employee	248	89	29
Insurance paid entirely by employee	25	9	3
No insurance	5	2	1

NOTE: Because of rounding, sums of individual items may not equal totals.

Eligibility requirements

To qualify for a disability pension, a worker must meet the plan's definition of total and permanent disability and, frequently, a service requirement. A minimum age may also be specified. These requirements often differ from those applicable to social security disability benefits.

Definitions of disability. As a rule, definitions of disability are designed to make benefits available only to workers whose incapacities require them to withdraw from the labor force. About three-fourths of the disability retirement plans defined disability either in the same way as social security (25 percent) or more restrictively (48 percent). The Social Security Act defines disability as incapacity for substantial gainful work at any job that exists to a considerable extent in the U.S. economy; such incapacity is expected to result in death or to last for a year or more.[7] Many private plans have a more restrictive definition, stating that persons must be disabled for "any type of occupation or employment." Consequently, workers meeting the eligibility requirement of nearly three-fourths of the private plans also met the social security test.

However, one-fourth of the disability retirement plans defined disability as occurring when an employee was unable to continue in his or her job with the company. Individuals meeting this criterion would not necessarily qualify for social security disability benefits.[8] But, half of the plans containing this relatively liberal definition offered a supplemental benefit which continued until eligibility for social security disability or retirement benefits or a specified age, such as 65, for persons not covered by social security. In this manner, they provided benefits more comparable to those obtained by employees eligible for social security disability payments.

Age and service requirements. Comparison of findings of this study with those of a 1966 Bureau analysis[9] indicates a growing emphasis on service rather than on age in defining eligibility for disability pensions. This brings private plans closer to the social security approach, which now includes only a service requirement. (A minimum age requirement for social security disability benefits was removed in 1960.) The following tabulation summarizes the various age and service requirements made by the plans.

Requirements	*Number of plans*	*Percent of plans*
Total	861	100
No age or service	138	16
Service only	499	58
Age only	9	1
Age and service	112	13
Meets qualification for long-term disability benefits	103	12

Almost three-fifths of the disability retirement plans in the 1980 study included a service requirement, but did not specify a minimum age for benefits. The average length of service required by these plans was 11 years. This was more restrictive than the social security stipulation which stated that an individual must be fully insured[10] and work in covered service 20 of the last 40 quarters (5 of the last 10 years).

Only 14 percent of the plans specified a minimum age; most combined age and service requirements, commonly age 45 with 10 years of service or age 50 with 15 years of service. The average age requirement in these plans was 46 years. Just 1 percent of the plans had only an age requirement, averaging 54 years.

The remainder of the plans (241) did not specify either an age or a service requirement *per se*. However, more than 40 percent of this group required that the eligibility for associated long-term disability plans be met, which most often had a minimal service requirement.

Waiting periods. Immediate disability retirement and long-term disability benefits typically were payable after an initial waiting period, usually 5 or 6 months. The waiting period, similar to the 5 months imposed by social security, is designed to ensure the validity of a claim before initiating payment of long-term benefits. However, most of the employees in the study were covered during all or part of the waiting period by sick leave or short-term accident and sickness insurance.[11]

Illustrative benefits

The following replacement rates illustrate typical disability retirement benefits among various types of plans and relate benefit levels to pre-disability earnings. Replacement rates—ratios of disability benefits to pre-disability earnings—were calculated for a hypothetical employee, age 55, retiring on a disability pension after 20 years of service under his or her current private pension plan. This is in contrast to assumed normal retirement at age 65 after 30 years. The hypothetical employee also had been covered for 30 years under social security, and met the social security definition of disability. Earnings equaled the average in the broad industry group in which employed, and followed a typical growth pattern over the years.

As noted, the majority of private pension plans giving immediate disability benefits were not coordinated with long-term disability plans and provided pensions unreduced solely for early disability retirement age. These plans, under the hypothetical conditions, would provide a pension estimated to average 21 percent of pre-retirement earnings. Adding social security payments—32 percent—total benefits would be just over half of earnings before disability.[12]

Replacement rates would vary under alternative benefit formulas. For example, a small portion of immediate disability retirement plans actuarially reduce benefits for early retirement age. These plans would commonly replace only 8 percent of the earnings of the hypothetical worker,[13] resulting in combined private pension and social security benefits of two-fifths of pre-retirement earnings. (In practice, replacement rates would deviate from those calculated here, depending on the actual age-service status of individual disabled workers.)

Replacement rates in the immediate disability benefit plans studied would generally continue unchanged after normal retirement age, except for the 50 percent increase in social security benefits provided for married employees with one wage earner in the family.[14]

Table 3. Full-time participants in private pension plans by provisions for disability retirement, medium and large establishments, 1980

[In percent]

Characteristic	Participants			
	All	Professional and administrative	Technical and clerical	Production
Total with disability retirement benefits	87	85	81	91
Minimum requirements for disability retirement				
Total	100	100	100	100
No age or service	16	18	21	13
Age only	1	1	1	1
Service only	61	51	48	70
Age and service	11	9	11	12
No age or service — meets qualification for long-term disability benefits	11	21	18	5
Benefit provisions				
Total	100	100	100	100
Immediate disability retirement	70	52	51	84
Unreduced normal formula	55	41	39	67
Reduced normal formula	7	6	7	8
Other than normal formula[1]	8	6	5	10
Deferred disability retirement	30	47	49	16
With benefits based on:				
Service when disabled	5	6	7	4
Service plus credit to normal retirement date	24	39	38	12
Service with some credit	2	3	4	1

[1] Includes flat amount benefits, dollar amount formulas, percent of unreduced normal benefits less social security, and percent of earnings formulas both with and without social security offsets.

Note: Because of rounding, sums of individual items may not equal totals.

The discussion of replacement rates under immediate disability retirement plans has ignored long-term disability benefits which are available to only a small fraction of the workers affected. However, these benefits are the primary private source of pre-retirement age earnings when deferred disability pensions are provided. In these instances, long-term disability payments—combined with social security—commonly yield either 50 or 60 percent of pre-disability earnings.

Under deferred disability pension plans, replacement rates change at the normal retirement age, both because of the addition of spouse's benefits under social security and the switch from long-term disability to private pension benefits. As observed above, pension benefits normally reflect service credit for the period of long-term disability benefits. For a worker retiring at age 55, an additional 10 years of credit would, on the average, raise the pension at age 65 from 21 to 30 percent of pre-retirement earnings; total yield—including social security—would then be 62 percent for a single employee and 78 percent if married.[15] Deferred and long-term disability benefit packages were more prevalent among non-negotiated plans for salaried personnel than among collectively bargained plans for hourly rated employees; therefore, white-collar workers tended to enjoy higher replacement rates than blue-collar employees when retiring on disability.

Participants in pension plans

Estimates of the extent of worker participation in pension plans of medium and large establishments are found in *Employee Benefits in Industry, 1980,* Bureau of Labor Statistics, Bulletin 2107. Table 3 contains pertinent findings of that study. The findings, it should be stressed, are based on review of the same data source as was analyzed for the current article. As shown in the table, 70 percent of all participants in pension plans with disability retirement provisions could receive immediate retirement benefits. The present analysis found immediate benefits specified in 68 percent of the plans. The closeness of the two calculations is striking, even after recognizing that both percentages were derived from the same survey data.

A breakdown of findings by occupational group is available for plan participant data only. Among the findings is that deferred disability benefit plans are markedly more common for white-collar than for blue-collar employees. □

FOOTNOTES

[1] The survey is conducted in a sample designed to represent all private sector establishments in the United States, excluding Alaska and Hawaii, employing at least 50, 100, or 250 workers, depending on the industry. Industrial coverage includes: mining; construction; manufacturing; transportation, communications, electric, gas, and sanitary services; wholesale and retail trade; finance, insurance, and real estate; and selected services. For additional details on the survey, see *Employee Benefits in Industry, 1980,* Bulletin 2107 (Bureau of Labor Statistics, 1981). See also Robert Frumkin and William Wiatrowski, " Bureau of Labor Statistics takes a new look at employee benefits" in this issue of the *Review.*

While the bulletin contains information for a universe of employees, data tabulations in this article are simple counts of the number of pension plans containing the characteristics under analysis. The data relate solely to the specific plans included in the study. No attempt has been made to project findings to the entire universe of pension plans.

[2] For an independent source of data on the incidence of disability retirement plans, see Jonathan Sunshine, *Disability,* Office of Management and Budget Staff Technical Paper, 1979, p. 113. An earlier BLS study of disability benefits, which excluded both related long-term disability insurance and deferred disability benefits, is reported in Stanley S. Sacks, "Disability Benefits Under Private Pension Plans," *Monthly Labor Review,* April 1966, pp. 389–95.

[3] *Employee Benefits,* pp. 6, 25.

[4] Normal retirement is the point at which a worker can retire and immediately receive all accrued benefits by virtue of service and earnings, without reduction because of age.

[7] For a more complete definition see *Social Security Programs in the United States,* (Department of Health, Education, and Welfare, Social Security Administration, January 1973), p. 31.

[8] There may be differences among private plans and the social security system with respect to coverage of disabilities associated with nervous conditions, alcoholism, drugs, self-inflicted injuries, and criminal activity.

[9] Sacks, "Disability Benefits."

[10] Generally, to be fully insured a worker must have one quarter of coverage for each year from age 21 to date of disability.

[11] *Employee Benefits* pp. 2–3.

[12] Coordination of private disability and social security benefits is accounted for in the calculation of the replacement rate for private benefits.

[13] The 8-percent replacement rate was derived by multiplying the unreduced normal retirement formula replacement rate of 21 percent by 39 percent. (As described above, plans actuarially reducing pensions for early retirement usually lowered benefits about 61 percent for quitting work 10 years before the normal retirement age.)

[14] Social security benefits are increased after each year in which the Consumer Price Index rises 3 percent or more. Such escalation is ignored in this analysis, because price changes cannot be accurately forecast.

[15] Both the 21-percent replacement rate for employees retiring under private pension plans with 20 years of service and the 30-percent rate for retirement after 30 years were derived by BLS from data in a study by James H. Schulz, Thomas D. Leavitt, Leslie Kelly, and John Strate, *Private Pension Benefits in the 1970's* (Bryn Mawr, Pa., McCahan Foundation, 1982). Schulz and his associates calculated replacement rates for retirements after varying lengths of service, for men and for women. Their calculations were based on an analysis of all pension plans in the 1979 BLS survey of employee benefit plans. The study calculated replacement rates for normal rather than disability retirement. However, because normal and disability retirement benefits are commonly based on the same formula, separate computations for disability retirement would not, in general, be appreciably different. For an earlier Schulz study, see James H. Schulz, Thomas D. Leavitt, and Leslie Kelly, "Private pensions fall far short of preretirement income levels," *Monthly Labor Review,* February 1979, pp. 28–32.

Bureau of Labor Statistics takes a new look at employee benefits

Initiated in 1979, annual survey provides a comprehensive study of benefit plan coverage and provisions in medium and large firms

ROBERT FRUMKIN AND WILLIAM WIATROWSKI

In 1981, employees in medium and large size establishments received, on average, about 10 paid holidays each year and nearly 16 days of paid vacation annually after 10 years of service. For 3 of 5 participants in a life insurance plan, coverage was based on earnings, with the prevalence of earnings-related plans much higher among white-collar employees. Seventy-one percent of the workers covered by the survey participated in health insurance plans that were fully paid for by their employers, and just under one-half also received employer-paid coverage for their dependents. Eighty-four percent of the employees were covered by private retirement pension plans (in addition to social security); 79 percent were in plans fully paid for by the employer.

As these statistics indicate, benefit plans are important elements in the typical employee compensation package. Employer outlays for legally required and private benefits, including paid leave, constituted about one-fourth of all expenditures for employee compensation in 1977, when this subject was last studied by the Bureau of Labor Statistics.[1] Moreover, the rate of growth in outlays for these benefits has substantially outpaced that for wages and salaries over the 40-year period since benefits began to gain prominence.

For many years, BLS tracked growth of benefit plans by studying both their provisions and their cost to employers.[2] Recently, BLS initiated an annual survey on the incidence and characteristics of employee benefit plans. This article describes the design, coverage, output, and availability of results from this new survey, which was first conducted in 1979.

The survey reports detailed characteristics of paid leave, insurance, and pension plans, yielding extensive data on employee benefit plan provisions. In addition, it produces estimates of the percent of employees covered by these plans or eligible for other benefits, such as profit sharing and educational assistance. Data are published for all full-time workers in three occupational groups: professional-administrative, technical-clerical, and production.

The program originally was designed to provide the Office of Personnel Management (OPM) with data on specific provisions of private sector employee benefits for a new approach to evaluating pay and benefits of Federal employees. This approach compares the Federal wage-benefit package with that in private industry.[3] (Current legislation requires that pay rates for Federal civilian workers, but not their benefits, be set on a comparability basis.) To meet OPM's needs, BLS developed a survey to provide extensive data on employee benefits, covering the same industry and size scope as the Bureau's annual Professional, Administrative, Technical, and Clerical Pay Survey that is currently used to evaluate Federal white-collar salary rates.[4]

Survey coverage

The employee benefits survey covers medium and large size private sector establishments in the contiguous United States, employing at least 50, 100, or 250 workers, depending on the industry. A subsample of

---

Robert Frumkin and William Wiatrowski are economists in the Division of Occupational Pay and Employee Benefit Levels, Bureau of Labor Statistics.

1,500 establishments from the Professional, Administrative, Technical, and Clerical Pay Survey, covering a wide range of manufacturing and nonmanufacturing industries, is selected to yield national estimates.[5] Data are collected by personal visits of Bureau field representatives to the sampled establishments. Respondents are requested to provide data on the coverage and details of selected types of plans for paid time off—lunch time, rest periods, holidays, personal leave, vacations, and sick leave. Rather than ask company officials for extensive information, brochures are collected which contain descriptions of insurance and pension plan characteristics. Data are also obtained from the Department of Labor's Employee Retirement Income Security Act files.[6] Information on approximately 7,400 paid leave plans and 6,800 insurance and pension benefit plans were collected for analysis in the 1981 survey. The use of brochures for plan analysis eliminates some of the burden put on the respondent's time. Insurance plans included in the survey cover health, life, accident and sickness, and long-term disability benefits. Retirement pension plans are also studied in detail. Besides plan provisions, the number of persons participating in each plan is reported. Information also is collected on the percent of employees eligible for other benefits, such as profit-sharing and stock plans, employee discounts, educational assistance, and parking.

Because of their complexity, insurance and pension plans require the recording of considerable detail on benefit provisions. For each benefit, several common provisions are examined: eligibility requirements, in the form of age or service attainment, or both, which are necessary to join the plan; the waiting period before certain benefits begin; and cost of the plan to the employee. Plans for which an employee pays 100 percent of the cost are not included in the study.

Health insurance plan analysis includes provisions for hospital room and board, surgical care, doctor visits, diagnostic x-ray, prescription drugs, private duty nursing, and mental health care. In each of these areas, analysis covers such limitations on benefits as deductible and coinsurance provisions, maximum dollar amount payable, and maximum numbers of days covered. In addition, each plan is carefully studied for details of dental coverage, maternity care, and scheduled dollar amounts payable for certain surgical procedures.

In the examination of pension plans, age and service requirements are studied for normal, early, and disability retirement and for pension vesting (the point at which an employee has the legal right to some pension benefit regardless of any further service under the plan). The most significant feature of pension analysis is the review of the benefit formulas. A variety of formulas is used to determine retirement payments; for example, percentage of the employee's career or terminal earnings, or a dollar amount for each year an employee is covered under the plan. Other pension provisions analyzed are survivor benefits, reductions in pensions for early retirement, supplemental payments provided in addition to normal retirement benefits, and cost-of-living adjustments.

Life insurance plans are reviewed for the amount of insurance, effects of disability on the insurance contract, and payment for accidental death. Accident and sickness insurance analysis includes the weekly benefit formula and duration of benefits, while for long-term disability insurance, the analysis includes benefit amounts and the integration of long-term disability insurance payments with other sources of income, such as social security, workers' compensation, and railroad retirement.

As for paid time off, the amount of lunch and rest time is recorded, together with the number of holidays and personal leave days granted each year. Analysis of vacation plans includes development of a schedule showing the variations in vacation time and payments by length of service. A similar schedule reports sick leave benefits, showing the number of days paid at full pay, partial pay, or both, as well as any waiting period before benefits may begin. For both vacation and sick leave, the incidence of cash-in or carry-over provisions, or both, for unused benefits is noted.

Limited data are collected on a number of other benefit plans which may add significantly to employee com-

Table 1. Full-time employees participating in selected benefit plans, medium and large establishments, 1981

[In percent]

Plan	All employees	Professional and administrative employees	Technical and clerical employees	Production employees
Paid time off:				
Holidays	99	100	100	99
Vacations	99	100	100	99
Personal leave	23	31	32	14
Lunch period	10	4	4	15
Rest time	75	60	76	82

Accident and sickness insurance	50	30	35	66
Fully paid by employer	41	22	26	56
Long-term disability insurance	41	61	52	26
Fully paid by employer	32	47	40	23
Health insurance for employee	97	98	96	97
Fully paid by employer	71	67	58	79
Health insurance for dependents	94	96	91	94
Fully paid by employer	48	45	36	55
Life insurance	96	98	95	96
Fully paid by employer	81	81	78	82
Retirement pension	84	88	85	82
Fully paid by employer	79	81	80	77

NOTE: Participation is defined as coverage by a paid leave, insurance, or pension plan. Employees subject to a minimum service requirement before they are eligible for a benefit are counted as participants even if they have not met the requirement at the time of the survey. If employees are required to pay part of the cost of a benefit, only those who elect the coverage and pay their share are counted as participants. Benefits for which the employee must pay the full premium are outside the scope of the survey.

pensation, such as profit-sharing, savings, and stock plans. The incidence of these benefits is examined separately for each employee group in each establishment. In addition, data are collected on the full or partial defrayment of cost for relocation allowance, recreation facilities, subsidized meals, parking, educational assistance, and employer-provided automobiles.

Availability of results

Major survey findings are reported annually in a bulletin published by BLS. The data and analysis center on the extent of employee participation in specified benefit plans and the provisions of these plans. The results of the pilot survey (in 1979) were published in 1980 in a report entitled *Employee Benefits in Industry: A Pilot Survey.*[7] This report contained 20 tables on worker coverage under various types of provisions for paid leave, insurance, and pension plans. Data collected in 1980 are contained in a more comprehensive bulletin, *Employee Benefits in Industry, 1980,* and reflect improvements in survey procedures and techniques, as well as changes in benefit practices in private industry.

A bulletin with estimates from the 1981 survey, entitled *Employee Benefits in Medium and Large Firms, 1981,* will be available in early September.[8] The bulletin contains details on three employee groupings demonstrated in accompanying tables: all employees covered by the survey (table 1); employees who participated in a particular type of benefit plan (table 2); and employees covered by a particular type of provision within a benefit area to provide a closeup look at an important feature (table 3). In addition, articles on the results of additional research on various benefit plan provisions, such as the article on disability retirement in this issue, are occasionally published in the *Monthly Labor Review.* Other articles in preparation include the growth of major medical insurance coverage and spouse benefits in pension plans.

Employee benefit data collected during the annual survey, including detailed plan provisions and participant figures, are available on magnetic data tapes.[9] In accordance with a pledge of confidentiality to survey respondents, all information that could identify a specific reporting establishment is removed. The tapes may be used to derive national estimates, similar to those presented in the bulletin, for those provisions on the data base that are not regularly tabulated by BLS.

Future direction

This research program on incidence and characteristics of employee benefits evolved from a pilot study to an annual survey and is continuing to expand. More intensive methods of analysis, as well as an increased number of data items, will lead to the publication of more comprehensive findings. Currently, such subjects as Health Maintenance Organization coverage, social security offset and integration with pension benefits, and differences in benefits for production and white-collar workers are being researched on the basis of data collected in the 1981 survey.

Collection of benefit data for 1982 includes, for the first time, information on post-retirement pension increases. In addition, more detailed information is being secured on health and life insurance coverage for retir-

ees. Unscheduled post-retirement pension increases are being analyzed along with pension formula provisions. Retiree health and life insurance coverage is now studied as well as the cost of this insurance to the retiree.

Information from this survey is helpful to a range of users, including personnel managers, employee benefit administrators, and industrial relations managers in private industry; unions; government agencies; academic researchers; and consultants, to name a few. To provide more comprehensive information to these users, BLS is investigating the possibility of expanding the scope of the survey to include small establishments and to cover some of the currently excluded industries. The survey's content and procedures will be evaluated continuously and additional analysis on private sector employee benefits will be developed as appropriate. □

FOOTNOTES

[1] *Employee Compensation in the Private Nonfarm Economy, 1977*, Summary 80-5 (Bureau of Labor Statistics, 1980), p. 3, table 1.

[2] For example, major provisions of benefit plans were summarized periodically and published in the Bureau of Labor Statistics' *Digest of Selected Health and Insurance Plans* and *Digest of Selected Pension Plans*. The series ran from 1955 to 1979. In addition, surveys of expenditures for employee compensation were conducted in the 1959–77 period. These programs have been discontinued because of budget constraints. The Bureau's Employment Cost Index, a quarterly measure of change in the rate of compensation, includes benefits as well as wages and salaries.

[3] The Office of Personnel Management processed the Bureau's 1979 and 1980 employee benefits data base through their total compensation comparability computer system. See Office of Personnel Management, *Total Compensation Comparability: Background, Method, and Preliminary Results*, July 1981, for a description of the total compensation comparability program.

[4] Technical specifications for the salary survey are in *National Sur-*

vey of Professional, Administrative, Technical, and Clerical Pay, March 1981, Bulletin 2108 (Bureau of Labor Statistics, 1981). The survey collects pay data for occupations defined to reflect duties and responsibilities of employees in private industry and that correspond to specific General Schedule grades in the Federal sector. Hence, the establishments selected for the survey are limited to those likely to have positions similar to those in the Federal service. For this reason, small establishments (fewer than 50, 100, or 250 employees, depending on the industry) and some industries (primarily in the services sector) are excluded from the scope of the PATC survey. Industrial coverage includes: manufacturing; mining; construction; transportation, communications, electric, gas, and sanitary services; wholesale trade; retail trade; finance, insurance, and real estate; and selected services. The selected services are limited to business services such as advertising, credit reporting and collection agencies, computer and data processing services, research and development laboratories, commercial testing laboratories, and management and public relations services; engineering and architectural services; noncommercial research organizations; and accounting, auditing, and bookkeeping services.

For an account of the sampling techniques, see the Technical Note in *Employee Benefits in Industry, 1980*, Bulletin 2107 (Bureau of Labor Statistics, 1981).

The Employee Retirement Income Security Act of 1974 requires benefit plan administrators to file summary plan descriptions with the Department of Labor. A summary plan description gives information on what the plan provides and how it operates and must be updated within 210 days after the end of the plan year (calendar or fiscal) in which the change is adopted.

A note on communications

The *Monthly Labor Review* welcomes communications that supplement, challenge, or expand on research published in its pages. To be considered for publication, communications should be factual and analytical, not polemical in tone. Communications should be addressed to the Editor-in-Chief, *Monthly Labor Review*, Bureau of Labor Statistics, U.S. Department of Labor, Washington, D.C. 20212.

Research Summaries

Weekly family earnings: a quarterly perspective

HOWARD HAYGHE

Most American families depend on wages and salaries for their livelihood. About 74 percent receive wage or salary earnings while another 7 percent obtain earnings solely from self employment. The rest—18.4 percent—report no earnings whatsoever, living instead on income from public or private pensions, social security, investments, personal savings, public assistance, or other sources.

A statistical series, introduced by the Bureau of Labor Statistics in 1980, provides information on the combined usual weekly wage and salary earnings of families on a quarterly basis.[1] Separate earnings statistics are also published for families with at least one unemployed member. Such information can be of value to policymakers and analysts concerned with how changes in employment, unemployment, and wages affect the economic well-being of American families.

Prior to 1980, the BLS had published statistics on usual weekly earnings by demographic characteristics, but only on an annual basis.[2] Such once-a-year observations were limited in their capacity to record the impact of economic changes. While an older monthly series on average weekly and hourly earnings from payroll records is more timely and provides detail by industry and geographic area, it does not include demographic or family information.[3]

This article discusses the newer, family-oriented earnings series, and focuses on the earnings situations of various categories of families at the end of 1981. Also discussed are developments in unemployment and inflation as they relate to family earnings.

Earnings by family type

There were about 60.1 million families in the United States in the fourth quarter of 1981. Of these, a little over 11 million had no employed members, more than 4.3 million had only self-employed workers, and another 4.2 million had both self-employed and wage and salary workers. The remaining 40.5 million families had only wage and salary workers (table 1). Because information is not collected on the earnings of the self-employed in the Current Population Survey, the following discussion focuses on those families with only wage and salary employment.

More than half of the 40.5 million wage-earning families contained at least two workers (table 2). At $585, the median weekly earnings of these families were nearly twice the earnings of families with one worker ($299). The fact that so many families now have two workers or more is directly attributable to the dramatic changes in women's labor force behavior over the past decade or so. During the 1970's—despite two recession periods—the number of working women grew by an average of about a million a year, and more than half of these women were wives. Also accelerating the trend toward two-worker couples was the tendency of couples to either postpone having children or to have fewer of them, and the willingness of mothers to enter or reenter the labor force sooner after childbirth than in the past. In March 1970, for instance, 24 percent of the wives with children under age 2 were in the labor force. Ten years later, the proportion was 39 percent.

Among married-couple families, about 19 million, or 58 percent of those with wage and salary earnings, had at least two workers in the fourth quarter of 1981. The median weekly earnings of such families were $601, compared with $336 for the 13.9 million one-worker families. Whether for one-earner or multiple-earner families, earnings were highest when the husband worked. For example, in one-earner families, median earnings were $383 when the husband worked, but were between $179 and $198 when the wife or some other family member was the only person employed. For those with at least two wage and salary workers, where the husband worked, usual median family earnings ranged from $574 to $780, depending on which other family members were also employed. In contrast, when the husband was not working, median family earnings were $380 and a little over $400.

Howard Hayghe is a labor economist in the Division of Labor Force Studies, Bureau of Labor Statistics.

As has long been the case, families maintained by women are characterized by very low earnings.[4] Moreover, the number of such families has grown considerably over the last decade; in March 1970, they numbered 5.6 million and by the end of 1981, they totaled 9.3 million. In the latter year, median weekly earnings of the 5.9 million families maintained by women with wage and salary workers were only about half those of married couples. The low earnings reflect both the small proportion of such families having two workers or more, as well as the generally low earnings of women who maintain their own families. Fewer than 3 out of 10 families maintained by women contained more than one worker.

To a certain extent, the low earnings levels of women maintaining families are a result of fewer years of schooling. A relatively high proportion who were in the labor force—over one-fourth—had not completed high school. And, as is well known, a high school diploma is frequently either the key to higher-paying jobs or to the additional training needed to compete for these occupations. Women maintaining families are also more likely than wives to have preschool children whose presence may restrict not only the mother's job-seeking efforts but her choice of jobs as well.

Race and Hispanic origin. Weekly earnings for black married couples ($412) were 84 percent of those of whites ($492), and Hispanic family earnings averaged 80 percent of white family earnings:

	White	*Black*	*Hispanic*
Married-couple families	$492	$412	$394
Families maintained by women	252	226	225
Families maintained by men	413	353	263

The earnings of black and Hispanic families that were maintained by women were 90 percent of those of their white counterparts.

The primary factor underlying the racial or ethnic differentials in earnings among married-couple families is the level of the husbands' earnings. White husbands working full time had median usual weekly earnings of $402 in the fourth quarter, compared with around $300 for black or Hispanic husbands. These earnings differences can be largely attributed to the fact that black and Hispanic husbands tend to work in occupations that are relatively low-paying. In March 1981, for example, about half of the black and Hispanic husbands working full time were operatives, laborers, or service workers, compared with one-fourth of the white husbands. In contrast, 37 percent of the white husbands were in professional or managerial jobs, compared with 17 percent of black or Hispanic husbands.

Table 1. Distribution of families by weekly earnings status, fourth quarter 1981

[Not seasonally adjusted]

Weekly earnings status	Number (in thousands)	Percent
Total families	60,077	100.0
No earnings	11,074	18.4
With earnings	49,002	81.6
With self-employed workers only	4,324	7.2
With wage or salary workers	44,678	74.4
Husbands, wives, or householders self-employed	4,166	6.9
All other families with wage or salary workers[1]	40,513	67.4

[1] May include some members (other than husband, wife, or householder) who were self-employed.

Table 2. Median weekly earnings by type of family, and number and relationship of workers, fourth quarter 1981

[Not seasonally adjusted]

Type of family and relationship of worker(s)	Number (in thousands)	Percent	Median earnings
Total families with wage or salary workers[1]	40,513	100.0	$442
One worker	19,304	47.6	299
Two workers or more	21,209	52.4	585
Married-couple families	32,920	100.0	496
One worker	13,948	42.4	336
Husband	11,077	33.6	383
Wife	2,227	6.8	179
Other family member	644	2.0	198
Two workers or more	18,972	57.6	601
Husband and wife only	13,204	40.1	574
Husband, wife, and other(s)	2,896	8.8	780
Husband and other family member(s)	2,318	7.0	603
Wife and other family member(s)	408	1.2	380
Other family members only	146	.4	405
Families maintained by women[2]	5,889	100.0	245
One worker	4,274	72.6	204
Householder	3,331	56.6	212
Other family member	943	16.0	176
Two workers or more	1,615	27.4	309
Families maintained by men[2]	1,704	100.0	405
One worker	1,082	63.5	327
Householder	857	50.3	366
Other family member	225	13.2	204
Two workers or more	622	36.5	545

[1] Excludes families in which the husband, wife, or householder is self-employed.

[2] No spouse present.

Note: Due to rounding, sums of individual items may not equal totals.

Inflation. For families with wage and salary earners, there was not as much loss in purchasing power in 1981 as during the year before (table 3). Between the fourth quarters of 1980 and 1981, median weekly earnings of families grew by 6.5 percent, while consumer prices (as measured by the CPI-W)[5] advanced by 9.4 percent. Families with two or more wage and salary workers nearly kept pace with rising prices but the earnings of one-worker families grew by only 4.5 percent in nominal terms and thus declined considerably in real terms. In the previous year, the increase in earnings (7.0 percent) offset only a little more than half the rise in prices (12.6 percent).

Earnings of married-couple families rose 9.0 percent from a median of $446 in the fourth quarter of 1980 to $486 in the fourth quarter of 1981. Weekly earnings of families where there was only one worker advanced by 5.0 percent while the earnings of two-worker families increased by 8.9 percent. In contrast, the usual weekly median earnings of families maintained by women advanced at a slower pace—7.0 percent.

Unemployment and family earnings

Unemployment grew rapidly during the closing months of 1981. The national unemployment rate jumped from 7.3 percent in August (a level which had been maintained throughout most of the calendar year) to 8.8 percent in December 1981. As a result, the number of families with unemployed members rose by about 800,000, or 14 percent, over the year ending in the fourth quarter of 1981. However, this increase was not as steep as the rise during the year ended in the fourth quarter of 1980 when the number of families with unemployed members grew by 27 percent.

In the fourth quarter of 1981, nearly 6.6 million families (over 10 percent of all families) contained at least one unemployed person; 1.8 million of these had no earners (table 4). In 7 out of 10 married-couple families with both wage and salary workers and unemployed members, the wife, son, or daughter (or some other member) was jobless, not the husband. Likewise, in nearly 90 percent of the families maintained by women and 75 percent of those maintained by men, the unemployed member was someone other than the householder.

Median usual weekly earnings for the 4.3 million families with both unemployed members and wage and salary workers in the fourth quarter were $312. Married-couple families reported median earnings of $335 a week—about 45 percent higher than the earnings of families maintained by women ($231) and 19 percent more than those of families maintained by men ($282).

For the most part, the earnings of families with unemployment depend on which family member is jobless. In married-couple families with an unemployed husband, earnings averaged $193 a week in the fourth quarter of 1981, compared with $338 for families with a jobless wife, and $493 when some member other than the husband or wife was unemployed. Furthermore, these medians varied considerably depending on which family members were working. For instance, in families with an unemployed husband and a working wife, earnings totaled $185 a week; but, when the wife was joined by other family workers, earnings were $332.[6]

INCREASINGLY, POLICY-ORIENTED ANALYSES and interpretations of the family earnings data will involve consideration of long-term demographic trends. For instance, as the population ages, growing numbers of families will contain persons past retirement age. Also, divorce and separation may continue to raise the proportion of families that are not married couples. Moreover, because of these trends as well as others related to family formation and dissolution, the number of mar-

Table 3. Total weekly wage and salary earnings of families by number of workers and family type, quarterly averages, 1979–81

[Not seasonally adjusted]

Type of family and number of workers	Median earnings			Percent change	
	1979 IV	1980 IV	1981 IV	1979 IV to 1980 IV	1980 IV to 1981 IV
Total families with wage or salary workers[1]	$388	$415	$442	7.0	6.5

ried couples is projected to increase more slowly in coming years. Such changes will undoubtedly have some impact on the family earnings profile. Thus, to understand the significance of changes in family earnings, analysts will need to examine the many demographic trends relating to families. ☐

FOOTNOTES

[1] The Bureau of Labor Statistics first released quarterly family earnings data in a press release entitled "New Data Relate Workers' Earnings to the Families in Which They Live," USDL 80–188, Mar. 27. 1980. The data continue to be published on a quarterly basis.

Earnings information is obtained from the Current Population Survey (CPS) only for families with wage or salary workers. The CPS is a sample survey of some 60,000 households (65,000 prior to May 1981) conducted monthly for the Bureau of Labor Statistics by the Bureau of the Census, with coverage in all 50 States and the District of Columbia. The survey provides basic information on the labor force, employment, and unemployment. The earnings information is collected each month from only a quarter of the sample and cumulated to provide quarterly and annual estimates. For a description of the procedures used to develop the weekly earnings data, see *Technical Description of the Quarterly Data on Weekly Earnings from the Current Population Survey*, Bulletin 2113 (Bureau of Labor Statistics, 1982).

[2] For an extensive discussion of these data, see *Weekly and Hourly Earnings Data from the Current Population Survey*, Special Labor Force Report 195 (Bureau of Labor Statistics, 1977).

[3] For a description of these data, see "Explanatory Note" in *Employment and Earnings*, January 1981, pp. 228–35.

[4] See Beverly L. Johnson, *Women Who Head Families*, Special Labor Force Report 213 (Bureau of Labor Statistics, 1978).

[5] The CPI-W refers to the Consumer Price Index for Urban Wage Earners and Clerical Workers. For a discussion of the general method of computing the Consumer Price Index, see *The Consumer Price Index: Concepts and Contents over the Years*, Report 517 (Bureau of Labor Statistics, 1978).

[6] It should also be noted that in 1981, on average, about 2.9 million people a week received unemployment insurance benefits which averaged a little over $100. Data on unemployment insurance recipients and amounts can be obtained from the U.S. Department of Labor, Employment and Training Administration, Unemployment Insurance Service, Division of Actuarial Services.

[7] For a discussion of demographic trends and how they will affect families by the end of the century, see George Masnick and Mary Jo Bane, *The Nation's Families: 1960–1990* (Joint Center for Urban Studies of MIT and Harvard University, 1980).

Analysis of work stoppages in the Federal sector, 1962–81

EUGENE H. BECKER

Since 1962, 39 work stoppages by Federal Government workers have been recorded by the Bureau of Labor Statistics and the Office of Personnel Management.[1] These stoppages occurred despite legislation explicitly prohibiting any type of strike activity by Federal workers.

The statutory prohibition began with the Lloyd-LaFollette Act of 1912. This act gave postal workers the right to organize, as long as they did not join unions asserting the right to strike.[2] Later, the strike ban was extended to cover other Federal workers and was codified in section 305 of the Labor-Management Relations Act of 1947, which read, in part:[3]

> It shall be unlawful for any individual employee of the United States or any agency thereof including wholly owned government corporations to participate in any strike. Any individual employed by the United States or any such agency who strikes shall be discharged immediately from his employment, and shall forfeit his civil-service status, if any, and shall not be eligible for reemployment for three years by the United States or any such agency.

Criminal penalties were added to the body of antistrike legislation in 1955.[4] In 1966, strike activity by Federal workers was further proscribed in the U.S. Code relating to Federal employment. The statutes prohibited the holding of a Federal job by persons who (1) participate in a strike, (2) assert the right to strike, or (3) belong to an organization that asserts the right to strike against the U.S. Government. The penalties for noncompliance were a fine of not more than $1,000, or a jail sentence of up to a year and a day. More recently, the ban on Federal strike activity has been codified in Title VII of the Civil Service Reform Act of 1978, which states that, for a Federal employee, " . . . it shall be an unfair labor practice . . . to call, or participate in, a strike, work stoppage or slowdown, or picketing of an agency in a labor-management dispute if such picketing interferes with an agency's operations, or . . . to condone any activity described in this paragraph by failing to take action to prevent or stop such activity . . . ."[5]

In 1971, the United Federation of Postal Clerks challenged the constitutionality of the laws proscribing strike activity by U.S. Government employees.[6] Among other complaints, the union contended that terms such as "strike" and "participates in a strike," language common to all the laws in question, are so vague as to be unconstitutional. However, the court held that there was no vagueness in the two terms, and that, indeed, they "occupy central positions in our labor statutes and accompanying case laws . . . ." Subsequently, the U.S. Supreme Court affirmed the ruling of the lower court that the laws under attack were constitutional.[7]

Work stoppages by Federal employees occurred as far back as 1835, when civilian blue-collar yard workers of the Navy Department in Washington, D.C., struck over working hours and for a "general redress of grievances."[8] After appealing to the Secretary of the Navy, but gaining little satisfaction, the workers returned to

Table 1. Work stoppages by Federal employees, 1962–81

Beginning date	Duration (calendar days)	Establishment and location	Union involved	Workers involved	Issues	Penalties
1962:						
Jan. 16	2	Tennessee Valley Authority, Paradise Power Plant; Drakesboro, Ky.	International Brotherhood of Electrical Workers (AFL-CIO)	190	Dispute over alleged unsafe working conditions	Employees returned to work without penalty after labor-management interviews.
Mar. 16	6	Tennessee Valley Authority, Paradise Power Plant; Drakesboro, Ky.	International Brotherhood of Teamsters, Chauffeurs, Warehousemen and Helpers of America (Ind.)	85	Assignment of truck driving duties to driver temporarily idle	Employees returned to work following labor-management interviews; three employees were suspended for 28 days.
June 20	10	Tennessee Valley Authority, Paradise Power Plant; Drakesboro, Ky.	International Brotherhood of Boilermakers, Iron Shipbuilders, Blacksmiths, Forgers and Helpers (AFL-CIO); International Association of Bridge, Structural and Ornamental Iron Workers (AFL-CIO)	350	Jurisdictional dispute over erecting slag tanks by employees represented by Iron Workers	Employees returned to work without penalty after labor-management interviews.
July 30	24	Tennessee Valley Authority, Paradise Power Plant; Drakesboro, Ky.	Sheet Metal Workers International Association (AFL-CIO)	2.500	Work assignment procedures and pay scales	Employees returned to work following labor-management interviews; the 85 sheet metal workers who began the stoppage were fired.
1968:						
Nov. 30	3	St. Elizabeth Hospital; Washington, D.C.	American Federation of State, County and Municipal Employees (AFL-CIO)	103	Alleged violation of position classification standards, work relationships, and laundering of uniforms of male nursing assistants	Issues settled through labor-management meetings. No penalties were imposed.
Dec. 11	8	Tennessee Valley Authority, Brown's Ferry Nuclear Plant; Athens, Ga.	International Brotherhood of Electrical Workers (AFL-CIO)	1.496	Suspension of entire electrical crew for violating published job rules	Employees returned to work without penalty following labor-management interviews.
Oct. 9	2	Hunter's Point Naval Shipyard; San Francisco, Calif.	Laundry and Dry Cleaning International Union (AFL-CIO)	80	Grievance procedures, working conditions, and disciplinary actions	Employees returned to work without penalties when shipyard agreed to immediate negotiations on a contract.
1969:						
June 18	2	Federal Aviation Administration; interstate	Professional Air Traffic Controllers Organization (AFL-CIO)	485	Alleged remarks made by head of FAA downgrading the role of controllers in policing air traffic	About 100 workers were temporarily suspended and PATCO lost its dues check-off privileges.
July 1	2	U.S. Post Office Department; New York City	National Association of Letter Carriers (AFL-CIO); National Postal Union (Ind.)	72	Size of second year wage increase	Employees called in sick; those found not to have been sick were placed on leave without pay for 2 weeks.
1970:						
Mar. 18	9	U.S. Post Office Department; nationwide	National Association of Letter Carriers (AFL-CIO); National Postal Union (Ind.); United Federation of Postal Clerks (AFL-CIO); The National Association of Special Delivery Messengers (AFL-CIO)	152.100	Retroactive pay increase, postal reform, and compression of pay schedule	All issues were settled by special legislation (PL 91-23), which provided for a 6-percent retroactive pay increase and the enactment of the Postal Reorganization and Salary Adjustment Act. No penalties were imposed.
Mar. 25	22	Federal Aviation Administration; nationwide	Professional Air Traffic Controllers Organization (AFL-CIO)	2.319	Employee reassignment, mediation of grievances, and union recognition	66 controllers were fired; about 1.800 were suspended 1 day for each day they stayed off the job.
May 25	1	U.S. Government Printing Office; Washington, D.C.	Columbia Typographical Union (AFL-CIO)/International Typographical Union	1.400	Manner in which the pay-setting formula was applied	Formula was revised. No penalties were imposed.
June 8[1]	7	U.S. Department of Agriculture; Alabama	American Federation of Government Employees (AFL-CIO)	Not known	Federal poultry inspectors refused to cross a National Farmer's Organization picket line for fear of physical harm	Inspectors who had not reported for work were considered absent without leave and were not paid for the time of their absence.
1971:						
April 5	10	Tennessee Valley Authority, Nuclear Project; Daisy, Tenn.	International Association of Bridge, Structural and Ornamental Iron Workers (AFL-CIO)	990	Work assignment	No information available.
May 4[1]	3	Department of Housing and Urban Development; Washington, D.C.	None	175	Alleged bias in employment practices	Some employees were charged with being absent without leave; others were warned about their actions.
June 17[1]	1	Naval Publication and Forms Center; Philadelphia, Pa.	Laborer's International Union of North America (AFL-CIO) was official representative but judged not to be involved	19	Dissatisfaction over workload and low pay	Involved workers were listed as absent without leave and given formal letters of reprimand; two supervisors were given 1-day suspensions.
June 23	5	Library of Congress; Washington, D.C.	None	35	Wages and working conditions	All employees suspended and ordered to report back to work; 13 who did not were fired.
1972:						
Jan.[1]	1	St. Elizabeth Hospital; Washington, D.C.	None	14	Position classification	Letter given to each employee spelling out the illegality and consequences of concerted actions against the Federal Government.
May 1[1]	5	Army Air Force Exchange; Charleston, Ohio	American Federation of Government Employees (AFL-CIO)	61	Job classification	Three employees were discharged; the others were not paid for the time they were out.
July 31[1]	1	Air Force base post exchange, Ft. Dix; McGuire, N.J.	None	60	Reduction in workweek from 40 to 35 hours	No penalties were imposed.
Sept. 24	12	Tennessee Valley Authority, Brown's Ferry Nuclear Construction Site; Athens, Ala.	United Association of Journeymen and Apprentices of the Plumbing and Pipe Fitting Industry of the United States (AFL-CIO)	460	Hiring of nonunion welders because union allegedly did not furnish TVA with union welders	Following labor-management interviews, 165 steamfitters were fired; others returned to their jobs.

Table 1. Continued—Work stoppages by Federal employees, 1962–81

Beginning date	Duration (calendar days)	Establishment and location	Union involved	Workers involved	Issues	Penalties
1974: Jan. 21	4	U.S. Postal Service: Jersey City, N.J.	American Postal Workers Union (AFL-CIO)	475	Change in working hours	U.S. District Court ordered workers to return to work and submit grievances to arbitration.
May 1[1]	2	Mare Island Naval Shipyard: California	Metal Trades Council	80	Change in pay structure	Employees were not paid for the days they were out.
May 9	3	Army and Air Force Exchange Service: Charlestown, Ind.	American Federation of Government Employees (AFL-CIO)	64	Protest over Department of Defense wage and salary survey	Employees returned to work without penalty following labor-management talks.
May 16[1]	3	Puget Sound Naval Shipyard: Washington	Metal Trades Council	60	Change in pay structure	Employees were not paid for the days they were out.
May 16	1	Washington National Airport Police: Virginia	International Brotherhood of Police Officers (NAGE)	33	New work rules prohibiting airport police officers from carrying home their service revolvers	No penalties were imposed.
1977: June 30[1]	1	Federal Aviation Administration: Los Angeles/Oakland, Calif.	None	16	Job classification	No penalties were imposed.
1978: July 21	8	U.S. Postal Service Bulk Mailing Center: New Jersey and California	American Postal Workers Union (AFL-CIO)	4,750	Dissatisfaction over terms of tentative agreement reached by union and Postal Service (main issue was size of wage increase)	About 125 workers were fired, 120 temporarily suspended, and 2,500 received letters of warning.
1979: Nov. 11[1]	1	Norfolk Naval Shipyard: Virginia	None	23	Pay rules in effect for trial run of new aircraft carrier	No penalties were imposed.
1980: April 21[1]	1	Department of Energy (Phoenix Western Area Power Administration): Arizona	None	60	Retroactive pay	Involved workers charged with being absent without leave.
June 20[1]	1	Department of the Interior (Grand Coulee Dam): Arizona	International Brotherhood of Electrical Workers (AFL-CIO)	183	Protest over size of Federal wage increase	No penalties were imposed.
June 25[1]	1	U.S. Army Corps of Engineers (hydroelectric dams in Oregon, Idaho, Washington, and Montana)	None	250	Protest over size of Federal wage increase	59 workers were reprimanded.
July 28	10	Tennessee Valley Authority, Phipps Bend Nuclear Plant: Surgoinsville, Tenn.	15 construction unions	900	Discharge of ironworker who allegedly struck supervisor.	42 workers were fired and 210 were suspended for 1 year.
Aug. 5[1]	1	Immigration and Naturalization Service: New York City	American Federation of Government Employees (AFL-CIO)	50	Immigration and Naturalization Service policy towards Iranians	No penalties were imposed.
Aug. 19[1]	1	Veterans Administration: Denver, Colo.	None	12	Disapproval of proposed pay raises	Involved workers charged with being absent without leave and reprimanded.
Sept. 17[1]	1	Federal Aviation Administration: Anchorage, Alaska	None	15	Recruitment policies	Involved workers charged with being absent without leave and reprimanded.
Dec. 15[1]	1	Veterans Administration Hospital: Los Angeles, Calif.	None	13	Disapproval of proposed special pay rates	Involved workers charged with being absent without leave and reprimanded.
Dec. 20[1]	1	Veterans Administration Hospital: San Francisco, Calif.	None	18	Pay comparability	Involved workers charged with being absent without leave and reprimanded.
1981: Aug. 3	81	Federal Aviation Administration: nationwide	Professional Air Traffic Controllers Organization (AFL-CIO)	12,500	Size of wage increase, length of workweek, and early retirement	About 11,500 workers who did not return to work during a presidentially mandated grace period were fired.

[1] Information provided by the Office of Labor-Management Relations of the Office of Personnel Management (formerly the U.S. Civil Service Commission).

their jobs. Between 1835 and 1937, there were at least 25 other stoppages by Federal employees, mostly civilian blue-collar workers of the Army and Navy Departments. These stoppages were "primarily strikes of mechanics for wage and hour improvements just as were strikes of such workers in the private sector."[9]

There were some exceptions to the general rule of Federal strikes by only blue-collar workers. For example, in 1907, 26 postal employees in Butte, Mont., struck over wage and reclassification issues. Eight of them were replaced when they failed to return to their jobs. *In 1937, a strike by Federal public health workers* ended when the national union, the American Federation of Government Employees, expelled the local for violating the no-strike clause in its constitution.

Between 1937 and 1957, the Bureau of Labor Statistics did not keep separate statistics on Federal strikes. Rather, it distributed such data among the industries in which the strike occurred. There were no Federal strikes during 1958–61. However, between 1962 and 1981, there were 39 stoppages involving Federal workers.[10] (See table 1.) No stoppages occurred in 8 of the years, and almost a quarter of them occurred in 1980.

All types of workers—blue-collar, white-collar, service, professional and technical, and laborers—have participated in strikes against the Federal Government. Eight of the 39 strikes involved construction workers at Tennessee Valley Authority installations, most of which were under construction at the time of the strike; four involved postal carriers and mail clerks, and the 1970 postal strike involving 150,000 workers was the largest Federal stoppage; air traffic controllers participated in five strikes, including an 81-day dispute in 1981, the longest Federal strike on record, which resulted in the firing of approximately 11,500 controllers; U.S. Naval shipyards had four stoppages; Army and Air Force post exchanges and the Veterans Administration each had three; and other Federal stoppages involved police, hospital workers (nurses' aides), custodial workers, typographers, and clerical workers. (See table 1.)

The issues surrounding Federal work stoppages were as broad as those found in private sector strikes. Stoppages occurred over safety issues, work assignments, jurisdictional questions, pay scales, job classification, working conditions, job rules, wages, union recognition, union security, working hours, and general grievances.[11] However, wages or wage-related issues were either primary or secondary causes of more than half the strikes, suggesting that Federal employees, like their counterparts in private industry, most often strike to improve their economic standing.

Penalties for Federal employees who engage in strikes include dismissal, suspension for various periods of time, written warnings and reprimands, and loss of pay. The following tabulation summarizes the penalties imposed in the 39 Federal work stoppages (multiple penalties were imposed in some stoppages):

Penalty	*Incidence*
Reprimand	9
Loss of pay	11
Temporary suspension	8
Discharge	8
No penalty	14
Information not available	1

For most Federal employees, the settlement of disputes is governed by the Civil Service Reform Act of 1978. This act gives the Federal Labor Relations Authority the responsibility of deciding unfair labor practices cases which, among other things, include engaging in or failing to prevent or stop a strike or work stoppage. For the Tennessee Valley Authority, however, the penalties are determined by a labor-management board, the Committee of the Tennessee Valley Trades and Labor Council. The council members interview all participants of a strike to determine: (1) the cause of the dispute; (2) the person(s) primarily responsible for the strike; (3) if the participant(s) may return to work; (4) what statement, if any, to include in the employee(s) records, and (5) the appropriate penalty against individuals found to have instigated the strike or who failed in their responsibility to attempt to prevent the action. Since 1962, the council has determined that dismissals were the appropriate remedy in 3 of the 8 TVA strikes, and suspensions for varying lengths of time in at least two strikes; in three others, the workers returned to work without penalty.

In 2 of the 4 postal strikes, workers were discharged or suspended for varying lengths of time and received letters of reprimand. No penalties were imposed in the other two stoppages, including the 9-day strike in 1970 which involved more than 150,000 postal employees.

Air traffic controllers were penalized in 4 of their 5 stoppages, having multiple penalties imposed in at least one stoppage. In addition, the Professional Air Traffic Controllers Organization temporarily lost its dues checkoff privileges as a result of their 1969 walkout and was decertified as the controllers' bargaining agent following their nationwide stoppage in 1981. This is the only incidence of decertification in any Federal dispute since 1962.

The most prevalent disciplinary action was being charged absent without leave and, in most cases, losing a day of pay for each day off the job. Written reprimands were the second most frequent penalty, followed by temporary suspensions and discharge. □

FOOTNOTES

[1] Information on 18 of the 39 stoppages was obtained from unpublished records of the Office of Personnel Management.

[2] 37 Stat. 555 (1912), 5 U.S.C. 652. The act states, in part, that membership in unions "imposing an obligation or duty . . . to engage in any strike or proposing to assist . . . in any strike against the United States" would result in grade reduction or loss of the employee's job. See David Ziskind, *One Thousand Strikes of Government Employees* (New York, Columbia University Press, 1940).

[3] Section 305 of the Labor Management Relations Act was repealed in 1955. However, at the same time, 5 U.S.C., Secs. 118p and 118r were enacted, retaining the prohibitions against strikes by Federal employees. These two sections were subsequently replaced in 1966 by 5 U.S.C., Secs. 2333 and 7311, and by 18 U.S.C., Sec. 1918.

[4] Title 5, Sec. 118r of the Unites States Code.

[5] Title VII had its antecedent in Executive Order 10988, which declared that an orderly and constructive relationship between unions and management was government policy. The number of Federal workers represented by unions increased substantially after this Executive Order was issued in 1962. See *Wage Chronology: Federal Employees Under the General Schedule Pay System, July 1924–October 1974*, Bulletin 1870 (Bureau of Labor Statistics, 1975), p. vii.

[6] The challenged laws were 5 U.S.C., Sec. 7311 (3) which forbids anyone from accepting or holding a Federal job who "participates in a strike;" 18 U.S.C., Sec. 1918 which makes strikes against the Federal government a criminal offense and provides penalties for violations; 5 U.S.C., Sec. 333 (par. C) which requires no-strike affidavits from Federal workers; and Executive Order 11491. See *United Federation of Postal Clerks v. Blount*, D.C.D.C. 1971, 325 F Supp. 879.

[7] 92 S.Ct. 80, 404 U.S. 802, 30 L.Ed.2d38.

[8] Ziskind, p. 24.

[9] Ziskind, p. 32; the last Federal strike noted by Ziskind occurred in 1937.

In addition, during 1917–20, when the United States vested control of the Nation's railroads and harbors in the Federal Railroad Administration, there were 46 stoppages involving railroad, marine, and waterfront employees. However, because of the temporary and emergency nature of Federal involvement in these industries, these stoppages are not considered bona fide Federal stoppages, nor are the large number of stoppages by participants in Depression-era Federal public works projects.

[10] These disputes include all Federal work stoppages lasting a shift, full day, or longer, and involving at least six workers. The Office of Personnel Management, in addition, takes account of all Federal job actions including informational picketing, walkouts (however short), sickouts and sitins, and other actions that may interrupt or have the potential to interrupt work routine. However, unless the job action met the Bureau's definition of a full shift and at least six workers, it was not included in the 39 stoppages noted. Stoppages culled from the Office of Personnel Management records are noted in the table.

[11] Federal law limits collective bargaining by Federal employees to nonwage issues. Exceptions to this rule, however, are air traffic controllers and employees of the Postal Service, Government Printing Office, and Tennessee Valley Authority. Seven of the twenty wage-related stoppages involved employees of these four agencies.

An overview of the population below the poverty level

The number of persons below the poverty level rose from 24.5 million in 1978, to 25.3 million (11.6 percent of the total population) in 1979. Statistically significant is the fact that the percentage of the population below the poverty level was unchanged.

Although the poverty rate for all persons was 11.6 percent, many groups had poverty rates well above or below the national average. For example, persons in families maintained by women with no husband present, had a poverty rate of 30 percent, compared with persons in families maintained by mean which had a poverty rate of only 6 percent. Despite the increase in the total number of persons below the poverty level during 1978–79, only a few of the major subgroups within the population experienced significant increases in the number of poor or the poverty rate.

There were 16.8 million whites and 7.8 million blacks below the poverty level in 1979—not significantly different from the previous year. As in earlier years, the poverty rate for whites (9 percent) was much lower than the rate for blacks (31 percent). Blacks accounted for 12 percent of the total U.S. population, but they made up 31 percent of the poverty population. About 2.9 million persons of Spanish origin were below the poverty level (11 percent of the poverty population) in 1979. Their poverty rate, 22 percent, was the same as in 1978.

The number of poor persons 65 years old and over increased from 3.2 million in 1978 to 3.6 million (a 15-percent poverty rate) in 1979. This increase probably occurred because their income (other than Social Security) did not keep up with inflation (which rose to 11.3 percent in 1979).

There were 15.7 million persons below the poverty level living in metropolitan areas. Of these, 9.5 million lived in central cities and 6.2 million lived in suburban areas. Poverty rates were the highest in 1979 for central city residents (16 percent) and lowest for suburban area residents (7 percent).

Of the 25.3 million persons below the poverty level in 1979, 42 percent lived in the South. The poverty rate for persons living in the South was 15 percent, compared with 10 percent for those in the North and West Region (combined regions).

The poverty level for families with a female householder, no husband present (30 percent) was much higher than the rates of married-couple families (5 percent) and families with a male householder, no wife present (10 percent). In 1979, the majority of white families below the poverty level were married-couple families (59 percent). By contrast, most poor black families were maintained by women with no husband present (72 percent). Nevertheless, for both races, the porportion of poor families maintained by women has increased substantially since 1970.

Finally, 5.6 million unrelated individuals (15 years old and over, living alone or with nonrelatives) were below the poverty level in 1979; 1.9 million men and 3.7 million women. This group increased by 400,000 between 1977 and 1979, and accounted for 12 percent of all persons and 22 percent of persons below the poverty level.

The full report, *Characteristics of the Population Below the Poverty Level: 1979*, U.S. Bureau of the Census, Current Population Reports, Series P-60, No. 130, is for sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. ☐

Major Agreements Expiring Next Month

This list of collective bargaining agreements expiring in September is based on contracts on file in the Bureau's Office of Wages and Industrial Relations. The list includes agreements covering 1,000 workers or more.

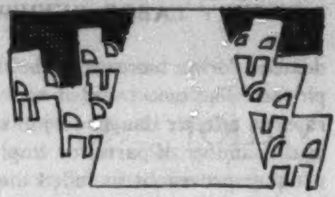
Employer and location	Industry	Labor organization[1]	Number of workers
Acme-Cleveland Corp., National Acme Co. Division (Cleveland, Ohio)	Machinery	Mechanics Educational Society	1,200
American Protective Services, Inc., Uptown Agreement (San Francisco, Calif.)	Services	International Union of Security Officers (Ind.)	2,200
Bronx Realty Advisory Board, Inc. (New York, N.Y.)	Real estate	Service Employees	11,000
Bruno Food Stores, Inc. and Food World, Inc. (Alabama)	Retail trade	Food and Commercial Workers	2,700
Caterpillar Tractor Co., Towmotor Corp., Central Agreement (Interstate)	Machinery	Auto Workers	25,000
Chicago and Suburban Refuse Disposal Association (Illinois)	Sanitary services	Teamsters (Ind.)	1,500
Chrysler Corp., 4 agreements (Interstate)	Transportation equipment	Auto Workers	75,300
Deere and Co. (Iowa and Illinois)	Machinery	Auto Workers	32,000
Deere and Co., John Deere Horicon Works (Horicon, Wis.)	Machinery	Machinists	1,200
Food Employers Council, Inc., 3 agreements (California)	Wholesale trade	Teamsters (Ind.)	7,000
FMC Corp., Bearing and Chain Divisions (Indianapolis, Ind.)	Machinery	Steelworkers	2,000
General Electric Co., Tube Products Department (Owensboro, Ky.)	Electrical products	Allied Industrial Workers	1,050
Greater New York Folding Box and Display Manufacturers Association (New York)	Paper	Paperworkers	3,000
GTE Sylvania (Ottawa, Ohio)	Electrical products	Electrical Workers (IBEW)	1,850
Jewel Companies, Inc., Jewel Food Stores Division (Indiana and Illinois)	Retail trade	United Retail Workers	14,000
Kaiser Steel Corp. (California)	Mining	Building and Construction Trades Council	1,150
Kelly-Springfield Tire Co. (Tyler, Tex.)	Rubber	Rubber Workers	1,150
Kern County Floor Covering Association (California)	Construction	Painters	1,700
Sanyo Manufacturing Corp., Forrest City, Arkansas Plants (Arkansas)	Electrical products	Electrical Workers (IUE)	1,900
Security Agencies, Uptown Agreement (San Francisco, Calif.)[2]	Services	International Union of Security Officers (Ind.)	2,000
Sportswear Agreement (San Francisco, Calif.)[2]	Apparel	Ladies' Garment Workers	3,000
Western States Field Construction Agreement (Interstate)[2]	Construction	Boilermakers	3,500

	Government activity	Labor organization[1]	
Florida: Dade County Fire Department	Fire protection	Fire Fighters	1,000
Dade County Police Department	Public safety	Dade County Police Benevolent Association	2,200
New York: New York City Board of Education	Education	Teachers	60,000
Ohio: Columbus Municipal Employees	Multidepartments	American Federation of State, County and Municipal Employees	4,000

[1] Affiliated with AFL-CIO except where noted as independent (Ind.).

[2] Industry area (group of companies signing same contract).

Developments in Industrial Relations



Pattern-setting agreement in garment industry

About 150,000 workers in the dress, coat and suit, and sportswear industries were covered by a settlement between the Ladies Garment Workers and various employer groups. The 3-year agreements are expected to set a pattern for 50,000 other workers and were effective on the June 1 termination date of the prior agreements. The initial 35-cent-an-hour wage increase was deferred to December 1, 1982, and will be followed by a 35-cent increase on June 1, 1983, and a 40-cent increase on July 1, 1984. Under the prior contracts, hourly pay rates ranged from $5.50 to $5.75.

A cost-of-living clause was established. Under the formula, the workers will receive a February 1984 pay adjustment of 10 cents an hour if the Consumer Price Index rises 8.5 percent between June 1, 1982, and December 1, 1983, plus 5 cents for each additional 0.5-percentage point rise in the index, subject to a 25-cent cap. Prior contracts did not have a cost-of-living clause but were subject to reopening if the CPI rose by specified amounts.

Other terms included an additional paid holiday and, for sportswear employees, a 1.5-percent (of payroll) increase in employer financing of benefits.

Employer groups involved in the settlement included the Affiliated Dress Manufacturers Association, Apparel Manufacturers Association, New York Coat and Suit Association, and New York Skirt and Sportswear Association.

Strike against American Standard ends

A 207-day strike against plants of American Standard, Inc., subsidiaries in Wilmerding and Swissvale, Pa., ended when the company and Local 610 of the United Electrical Workers resolved the last major issue by agreeing on grievance-arbitration procedures for determining if the company was justified in firing 22 of the strikers for alleged picket line violence. Other major issues were company demands for increased productivity and installation of a computer system to aid in keeping inventories and managing the flow of work.

In regard to the productivity issue, American Standard said the settlement provides that, "in general, incentive employees will have to meet or exceed output standards before prior earnings are guaranteed; however, they will now have the opportunity to increase their earnings significantly depending on their output."

The union said that it had agreed to installation of the computer system after the company promised not to use it for pinpointing high incentive earnings or for any time study purposes.

The 3-year accord also limited workers at the Westinghouse Air Brake Co. plant in Wilmerding to two job transfers a year. Previously, they could bid on jobs at will, which disrupted production, according to management officials. American Standard agreed to conduct programs to train senior employees for job openings at its WABCO and the Union Switch and Signal plants.

The settlement, which covered 3,800 workers at the two plants, provided for a total of 85 cents an hour in specified wage increases; for retention of the provision for automatic cost-of-living pay adjustments, subject to a limit of $2.32 an hour over the 3-year term; for establishment of a dental care plan; and for improvements in pensions and other benefits.

Airline strike ends

A 3½-week strike against Northwest Airlines ended when 3,600 mechanics, baggage handlers, food-service workers, and security personnel ratified a 38-month contract. The agreement, negotiated by the International Association of Machinists, called for wage increases of 9 percent retroactive to November 1, 1981, 9 percent on January 1, 1983, and 5.5 percent on January 1, 1984.

The parties compromised on the productivity concession Northwest had sought. In exchange for greater flexibility in job assignments, the company dropped its

"Developments in Industrial Relations" is prepared by George Ruben of the Division of Developments in Labor-Management Relations, Bureau of Labor Statistics, and is largely based on information from secondary sources.

demand for an increase in the number of part-time employees. The union said it viewed the changes in work rules as a lesser danger to job security than an increase in the number of part-time employees.

Other provisions included increased shift differentials and pay premiums for employees holding Federal aircraft repair and maintenance licenses, and a new combined regular medical and major medical lifetime coverage of $1 million, instead of the previous total of $500,000.

Paper mill institutes 'gainsharing' plan

More than 2,000 employees of Crown Zellerbach pulp and paper mills in Camas and Port Townsend, Wash., were covered by a new "gainsharing" plan developed under provisions of a 5-year labor contract negotiated in mid-1981. Crown Zellerbach said that the plan will pay the workers extra money for productivity improvements achieved by "working smarter, not harder."

The employees, who are represented by the Association of Western Pulp and Paper Workers union, received an initial payment of $500 because they accepted the plan before the June 1 deadline. In the future, the size of the annual lump-sum payments will be based on the hours worked and the cost savings resulting from a productivity formula. The formula will include such factors as the output of paper machines, reduction of waste, and reduction of purchased energy. Regardless of the results, the workers will receive at least 10 cents for each hour worked during the 12-month period.

Early negotiations possible in steel industry

The way was cleared for a possible early settlement in the steel industry when presidents of Steelworkers' local unions voted 263 to 79 to begin "discussions [with the major producers] for the purpose of exploring possible solutions" to economic conditions and resulting layoffs plaguing the industry.

Union president Lloyd McBride said that he was not "ruling in or ruling out anything" regarding possible wage-and-benefit concessions or new contract talks. The union's current 3-year agreements with the eight Coordinating Committee Steel Companies are scheduled to expire in August 1983.

In a related development, U.S. Steel Corp. reduced salaries of its 20,000 management level employees by at least 5 percent, effective July 1. In addition, the company froze the cost-of-living allowances of 7,000 nonmanagement employees; previously, the company had granted quarterly pay adjustments to these employees similar to those resulting from the provision in the Steelworkers' contract.

The company also said that some benefits would be reduced for all of the white-collar workers. The change included elimination of the fifth week of paid vacation for long-service employees, two paid holidays a year and a dental care plan, as well as modifications of other health benefits. Earlier in the year, other major stee companies had imposed similar changes for nonunion white-collar workers.

Wage-and-benefit concessions

The results of adverse economic conditions were no confined to the steel industry. Various companie moved to alleviate problems, either through bargaining with unions or by instituting wage-and-benefit reductions or deferrals for nonunion workers.

- In Billings, Mont., 350 employees of Pierce Packing Co. agreed to a 1-year wage reduction of $1.90 an hour, with the lost money to be repaid over a 4-year period. The workers, who are represented by two locals of the United Food and Commercial Workers and a local of the Operating Engineers, also agreed to a 1-year moratorium on pay increases, including cost-of-living adjustments; to take three holidays withou pay; and to changes in work rules intended to increase productivity. Similar changes were instituted for salaried employees, who are not union-represented. The company said the changes were needed to counter a slowdown in its sales of pork products.
- In the nonferrous mining industry, Hecla Mining Co of Wallace, Idaho, announced a pay reduction ranging from 5 percent for employees earning less than $17,000 a year to 15 percent for top management The reduction was 10 percent ($2,080 a year) for miners earning the starting rate of $10 an hour Among the workers affected were 100 gold miners and 30 lead and silver miners. The cut did not apply to 250 lead and silver miners represented by the United Steel Workers. It also did not apply to 22 nonunion lead, zinc, and silver miners whose pay had already been cut 10 percent. Hecla President William A. Griffith said the pay cuts were required because of severe declines in mineral prices.
- Barber-Greene Co. cut salaries by 3 to 9 percent for its 900 office and management employees in the Uni ed States and Canada. The company said that salaries will be frozen at the reduced level "for the indefinite future" and that some of its white-collar worker would be laid off over the next 2 months. The company, which had already cut its hourly work force b 30 percent within the last year, said the white-colla actions were necessitated by slumping demand for i road construction, mining, and industrial machinery.
- The Hesston Co., a Kansas manufacturer of farm an oil field equipment, froze the pay of 200 cleric workers and cut the pay of 350 other white-coll

workers by 5 percent. Hesston said the moves were needed "to reduce costs that cannot be recovered in today's economic conditions." The changes did not affect 950 employees represented by an independent union.

- In Columbus, Ind., Cummins Engine Co. cut the pay of all its salaried employees in the United States by 6 percent and said it was considering further measures to reduce costs. This was in addition to a cut 3 months earlier for officers of the company. The company said that it was discussing wage concessions with an independent union representing office workers in the Columbus area, but was not discussing cuts with the Diesel Workers Union, another independent union, because "we've already had lots of layoffs among the production workers it represents."
- In the rubber industry, B.F. Goodrich Co. announced that it was cutting the pay of 10,000 higher-salaried employees and freezing the pay of several thousand others. John D. Ong, chairman and chief executive officer of the company, said "the actions are precautionary in nature and represent our commitment to managing our way through this difficult period." The cut, limited to employees earning at least $20,000 a year, was 15 percent for members of Goodrich's management committee, 10 percent for other executives, and 5 percent for other employees. The company also said that it would not grant pay increases to salaried workers and was eliminating a week of paid vacation for those eligible for 3 weeks in 1983.
- Exxon Corp. announced that it planned to reduce expenses 15 percent and that 60 percent of this would be achieved through personnel cutbacks. The oil company said that the staff reduction would be achieved through voluntary retirements.
- In Grand Haven, Mich., employees of the Bastian Blessing Co. agreed to a $1-an-hour reduction in future wage-and-benefit improvements that had been scheduled under a 3-year contract negotiated in February. Under the concession plan, average pay will go from $9.30 an hour to $9.32 by the end of 1983, and to $10.12 by the end of the 3-year contract term. The 300 employees represented by Sheet Metal Workers Local 430 accepted the agreement after being told that the cost reduction was necessary to assure purchase of the plant by local investors, including some officials of the plant, which makes restaurant equipment. The purchase negotiations were being conducted with the plant's parent firm, Bastian Industries, Inc. The Grand Haven plant had been experiencing financial problems and layoffs because of the loss of a major account. The purchase group assured the employees that completion of the sale would result in recall of the workers.
- The Aluminum Company of America froze the salaries of its top 1,800 managers and cut in half the rate at which 9,500 other salaried employees accrue points toward salary increases based on the cost-of-living, performance, and other factors. Company spokesman Robert Larson described the move as "a short-term tactic to conserve cash and a long-term strategy to bring all our salaries into a more competitive relationship with other manufacturing companies."
- The Kirsch Co., a maker of home furnishings hardware, and Local 797 of the Automobile Workers revised their existing contract to provide for a wage freeze extending to June 1985. The accord, which was ratified by a 410 to 41 margin, also called for reductions in some benefits. Despite these cost-saving changes, the Sturges, Mich., firm gave no assurance that more layoffs or a plant closing could be averted. Kirsch already had 300 production workers on layoff.
- In Lockport, N.Y., 430 employees of Guterl Special Steel Corp. agreed to a package of wage-and-benefit reductions expected to save the company $1.5 million. Workers will return to "normal" wage-and-benefit levels in October 1983, a week before the expiration of Guterl's current contract with Local 2857 of the United Steelworkers. In exchange for the aid, the company agreed to return to employees the dollar value of the concessions, plus 7 percent interest, beginning October 1, 1984, if financial conditions permit. Guterl president Douglas K. Pinner said the union aid was necessitated by "a severely depressed economy, coupled with unconscionable levels of imports approaching 50 percent in some steel products."
- In the construction industry, 200 plumbers in Connecticut agreed to work on housebuilding projects at 65 percent of their usual pay rate. The agreement between the Naugatuck Valley Mechanical Contractors Association and Local 22 of the Plumbers and Pipefitters specified that the special rate would apply to work on single family homes, garden apartments, and condominiums. The rate also applies to small warehouses and commercial facilities.
- Caterpillar Tractor Co. froze the salaries of its management and weekly salaried employees, and suspended their quarterly cost-of-living increases, merit raises, and payments in lieu of unused vacation time. The move affected 13,800 management employees and 9,600 others, such as secretaries and technicians. The heavy equipment manufacturer also was offering cash retirement inducements to management employees at least 58 years old.
- Massey Ferguson announced that it was deferring payment of part of the salaries of its 3,000 North American white-collar employees until October. The deferred amount, expected to total $6 million,

amounted to 25 percent of pay for senior employees and 20 percent for others. The Canadian company indicated that 2,000 of the affected workers are located in the United States, primarily in the Des Moines, Iowa, and Detroit, Mich., areas. Earlier in 1982, Massey-Ferguson's production workers in the United States agreed to wage concessions totaling $10 million over a 30-month period. These workers are represented by the United Automobile Workers.

- Clark Equipment Co. announced plans to cut 700 employees from its white-collar staff of 5,200 by November 1. Some of the reduction would be accomplished by offering special retirement incentives to employees who are age 55 with at least 10 years of service. About 500 employees were eligible for the program. The construction equipment maker also disclosed that it was undertaking a study to determine if some of its 11 North American plants should be closed.

Supreme Court rules on subcontracting clauses

In the area of collective bargaining, the Supreme Court ruled that a construction union can negotiate provisions requiring contractors to do business only with subcontractors that recognize the union. The case resulted from 1959 amendments to a Federal law that prohibited such subcontracting clauses in all industries except construction. Despite this language, doubts about the exemption had continued because, in 1975, the court had taken a narrow interpretation of the exemption.

In the recent unanimous ruling, written by Justice Thurgood Marshall, the court said that construction unions can seek subcontracting clauses in the normal course of collective bargaining.

In its arguments in the case, which involved labor disputes in Southern California and in Oregon, the industry representatives involved contended that such clauses should apply only when needed on specific projects to preclude union and nonunion workers from working side by side.

Court bans 'nonunion' contributors to campaigns

A union can prohibit outsiders from contributing to union leadership campaigns, according to the Supreme Court. The case resulted from the 1977 race for leadership of the Steelworkers union between Lloyd McBride, who was endorsed by most of the incumbent officers and won the contest, and Edward Sadlowski, who drew substantial financial contributions from "outsiders." Later, in 1979, the union's convention adopted a rule prohibiting outside contributions.

Sadlowski then challenged the rule in court, contending that it violated provisions of the Labor-Management Reporting and Disclosure Act guaranteeing free speech to union members.

Writing for the majority, Justice Thurgood Marshall said that the act's free speech guarantee was not as broad as the guarantee of the First Amendment to the Constitution and that the union need only show—as it had—that its rule was "rationally related" to its desire to reduce outside interference.

Justice Byron R. White, writing for the minority, said that the outsider rule was unreasonable because Congress was concerned about corrupt and entrenched union leadership when it passed the 1959 law. Continuing, he said that restrictions such as the outsiders rule "are a far cry from the free and open elections that Congress anticipated and are wholly inconsistent with the way elections have been run in this country."

3M Company settles sex discrimination suits

Ending years of litigation, Minnesota Mining & Manufacturing (3M) Co. settled several sex bias suits by agreeing to pay $2.3 million to 2,350 women. The Equal Employment Opportunity Commission said that the suits had charged the company with discrimination in job assignments, wages, promotions, transfers, and other employment policies.

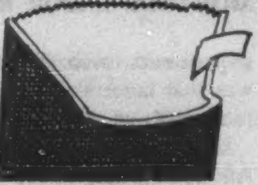
Under the settlement, the company agreed to give 1,350 female employees about $1.5 million in back pay, plus interest. The company also agreed to help the women attain higher-paying jobs by offering them job counseling, posting job vacancies, and paying for job-related courses.

Locals of the Oil, Chemical and Atomic Workers and the Grain Millers unions, which were codefendants in the suits, will set up committees to handle discrimination issues at the five plants.

The settlement also required 3M to pay $525,000 plus interest to some 1,000 women it had forced to take maternity leave 4 months before they were scheduled to give birth. This policy was essentially ended in 1973.

3M said that it settled because the suits were consuming a great deal of management time, and that now it could concentrate on its affirmative action programs for hiring, training, and promoting women.

Book Reviews



Portrait of a leader

George Meany and His Times: A Biography. By Archie Robinson. New York, Simon and Schuster, 1981. 445 pp. $18.75. Single copy, $12.50 postpaid, AFL-CIO Books, P.O. Box 37473, Washington 20013.

George Meany, scowling through the thick smoke of a cigar, uttering defiant and sometimes ungrammatical challenges to leaders of government and industry, probably would have been a casting director's ideal "labor boss."

But the George Meany of this book, passionately devoted to democratic institutions, arch foe of communism and corruption, champion of civil rights and social justice, is difficult to fit into the "labor boss" stereotype.

George Meany not only authorized this biography, he collaborated actively in its preparation during 4 years of weekly taped interviews with the author. Not surprisingly, then, the book is less a searching evaluation than the recollections of a celebrated leader at the end of his career.

Archie Robinson got to know George Meany during 37 years as a labor reporter for the *Detroit News* and *U.S. News & World Report.* Because he relies heavily on speeches and taped recollections, his admiring portrait accurately reflects Meany's direct—and often blunt—manner. But the virtue of telling Meany's story in Meany's own words is offset at times by Robinson's practice of reporting events by stringing together Meany quotations, with minimal or self-conscious, "as he recalled for this book," transitions. This tends to limit the reader to Meany's view of events, where the inclusion of other views might have provided fuller understanding.

An example of this limitation is the account of Meany's frustration with the World War II stabilization program which led to an attack on the Bureau of Labor Statistics. Robinson quotes at length from Meany's statements accusing BLS of not doing an adequate job of measuring the cost of living, charging that BLS "has laid aside its function as an impartial research agency interested only in securing and presenting the facts and has identified itself with the objectives of a specific political administration," and denouncing Acting Commissioner Ford Hinrichs as "a bureaucratic monkey on a stick who moves up and down in conformity with the dictates of the administrative wage policy." Robinson's readers don't learn that other participants in that dispute, including some of Meany's trade union colleagues, found his attacks on BLS unwarranted.

Robinson traces Meany's rise from a high school dropout who failed in his first attempt to pass the journeyman plumber examination, to popular business agent for his Bronx union local, chief lobbyist and president of the New York State Federation of Labor, secretary-treasurer of the American Federation of Labor, and finally, AFL-CIO president. The book is at its best when it describes Meany's relationship with eight presidents of the United States and with Walter Reuther. (After one of Reuther's attacks on Meany as "a complacent custodian of the status quo," Meany joked to reporters that "I'm now signing my letters 'sincerely and complacently yours'.")

Robinson describes some events not often remembered, including the fact that, while still in New York, Meany led a successful strike against the New Deal relief agencies that wanted to pay less than prevailing rates on Works Progress Administration construction projects.

The book also documents Meany opinions that will surprise some readers:

On the split in the labor movement in the 1930's: "There was no good trade union reason for the split . . . (Franklin D. Roosevelt) was going to seek more active political support (in the 1936 election) and he didn't figure he would get it through the AFL Executive Council, which was fairly conservative. . . . The industrial union idea was a bugaboo designed to cover up the political motives of the sponsors of the CIO."

On forming a labor party: "When you set up a labor party—I don't care where it is—and you tie yourself to a labor party, you are saying, in effect, we not only want better conditions for the people we represent, we not only want to raise the standard of life, we want to run the country. (Samuel) Gompers took the position that it was not our job to run the country. . . . The Gompers' philosophy was not to be nonpolitical, it was to be nonpartisan. The Gompers' philosophy basically was that labor should not tie itself to a political party in any way at all. That is still our policy . . . ."

On lobbying: "You never beg and you never threaten. And always keep in the back of your mind that the other guy may be right."

On being an economist: "I look back when I was a high school dropout. I think now that if I had gone on, I might have wound up being an economist. And to me, that's kind of a sad profession. Although it is the one profession in which you can gain great eminence without ever being right."

In pursuing plumbing and union leadership careers instead of economics, George Meany was often right and gained great eminence as well. This book tells that story and tells it well.

—HENRY LOWENSTERN
Editor-in-Chief
Monthly Labor Review

Excluding unions

Preventive Labor Relations. By John G. Kilgour. New York, AMACOM, A division of American Management Associations, 1981. 338 pp. $24.95.

In recent years, a steady flow of books and articles have been published to assist employers in preventing unions from invading their businesses and activities. These publications, together with a series of seminars and intensified activity by consultants advising employers on how to avoid unions, have contributed to a climate of tension and distrust in labor-management relations. There is little doubt that some of these antiunion efforts have caused great concern in the organized labor movement.

This book may irritate some labor union members and officers merely because it discusses ways of preventing labor unions from organizing the unorganized. It is not, however, a vitriolic attack on labor unions. It begins with the assumption that the vast majority of nonunionized employers would prefer to remain free of unions. It then proceeds to cover a number of areas in which employers can take action to keep unions out. Throughout the book, however, the author stresses the need to adhere to the rules of collective bargaining and personnel administration.

Basically, "preventive labor relations" encourages early attention to organizing efforts, establishing effective communication links to detect early organizing moves, and establishing a basis for meeting and conferring with employees on a regular basis. Employers are cautioned not to overpublicize their efforts because employees could become more aware of union activities th would otherwise be the case.

Particular suggestions are made with respect to pla location (where unions have traditionally experienc difficulties in organizing workers); a mix of workers include groups generally opposed to unions; and esta lishment of larger work units which the author believ will help oppose organizing efforts because, he say unions are less successful in organizing larger uni This last point conflicts with recent releases by the N tional Labor Relations Board indicating that unio have been most successful in organizing larger unit The author may be thinking of larger bargaining uni with a diverse work force consisting of a sizable numb of workers from groups not thought to be susceptible t union organizing drives.

The author considers effective screening and hiring o workers to be one of the most essential aspects of pre ventive labor relations. He cautions, however, that car must be taken to avoid the legal pitfalls of such selec tive personnel practices. It would seem to this reviewe that the official use of such practices can be construe as a violation of existing law, especially since the book suggests that certain "protected" groups are more prone to join unions than are members of other groups. Among the groups mentioned by the author as being less likely to join unions are retired military personnel, older people, part-time and temporary workers, and certain ethnic-racial groups who believe that unions have not acted in their best interests. One must question this kind of selection policy and practice on another basis. Will the organization get the best possible work force? The point made by the author is that a carefully selected mix of workers can help keep unions out.

Kilgour emphasizes two important points. For example, he says the best way to keep unions out is to practice fair and effective personnel administration. This means not only the personnel office but each manager, who, in effect, is a personnel manager. If workers believe that the organization's personnel policies and practices are superior to what can be expected in a unionized environment, there will be little or no incentive to join a union.

If, however, union organization drives get started, it is easier to defeat them if the organization has advance warning. Open door policies practiced by managers, exit interviews, attitude surveys, detection of increased absenteeism or turnover, and so forth, can help serve as an early warning system. Again, it is important, says the author, not to show too much activity or concern because this might precipitate unions to take action earlier than planned, or, it can help to stir up employees to seek outside assistance.

If organizing drives do get started, employers are cautioned to operate within the rules. This is not to suggest a "cave-in," but the author says that employers should manage to get this viewpoint across, and to do all that is legally possible to keep the union organizing effort from succeeding. This involves getting information to employees, timing events to conform to the organization's needs, and striving to gain the best strategic advantage possible.

Finally, the author suggests that if a certification election results in a union victory, management must be tough, effective negotiators. Thereafter, they should administer the contract fairly and consistently and continue to manage effectively. The fight is not necessarily over. Changes can and do occur.

This book can be helpful to employers in planning strategy to prevent unions from organizing workers. It has a sensible tone and approach, with proper caution. It can also be helpful to union organizers in planning their strategy. On balance, this book would be useful to both management and labor.

NOTES ON CURRENT LABOR STATISTICS

This section of the *Review* presents the principal statistical series collected and calculated by the Bureau of Labor Statistics. A brief introduction to each group of tables provides definitions, notes on the data, sources, and other material usually found in footnotes.

Readers who need additional information are invited to consult the BLS regional offices listed on the inside front cover of this issue of the *Review*. Some general notes applicable to several series are given below.

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might otherwise mask short-term movements of the statistical series. Tables containing these data are identified as "seasonally adjusted." Seasonal effects are estimated on the basis of past experience. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years.

Seasonally adjusted labor force data in tables 2–7 were revised in the March 1982 issue of the *Review* to reflect experience through 1981. The original estimates also were revised to 1970 to reflect 1980 census population controls.

Beginning in January 1980, the BLS introduced two major modifications in the seasonal adjustment methodology for labor force data. First, the data are being seasonally adjusted with a new procedure called X-11/ARIMA, which was developed at Statistics Canada as an extension of the standard X-11 method. A detailed description of the procedure appears in *The X-11 ARIMA Seasonal Adjustment Method* by Estela Bee Dagum (Statistics Canada Catalogue No. 12-564E, February 1980). The second change is that seasonal factors are now being calculated for use during the first 6 months of the year, rather than for the entire year, and then are calculated at mid-year for the July-December period. Revisions of historical data continue to be made only at the end of each calendar year.

Annual revision of the seasonally adjusted payroll data shown in tables 11, 14, and 16 were made in August 1981 using the X-11 ARIMA seasonal adjustment methodology. New seasonal factors for productivity data in tables 30 and 31 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month to month and from quarter to quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average All Items CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100. For example, given a current hourly wage rate of $3 and a current price index number of 150, where 1967 = 100, the hourly rate expressed in 1967 dollars is $2 ($3/150 × 100 = $2). The resulting values are described as "real," "constant," or "1967" dollars.

Availability of information. Data that supplement the tables in this section are published by the Bureau of Labor Statistics in a variety of sources. Press releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule given below. The *BLS Handbook of Labor Statistics*, Bulletin 2070, provides more detailed data and greater historical coverage for most of the statistical series presented in the *Monthly Labor Review*. More information from the household and establishment surveys is provided in *Employment and Earnings*, a monthly publication of the Bureau. Historically, comparable information from the establishment survey is published in two comprehensive data books—*Employment and Earnings, United States* and *Employment and Earnings, States and Areas*, and their annual supplements. More detailed information on wages and other aspects of collective bargaining appears in the monthly periodical, *Current Wage Developments*. More detailed price information is published each month in the periodicals, the *CPI Detailed Report* and *Producer Prices and Price Indexes*.

Symbols

p = preliminary. To improve the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.
r = revised. Generally, this revision reflects the availability of later data but may also reflect other adjustments.
n.e.c. = not elsewhere classified.

Schedule of release dates for major BLS statistical series

Series	Release date	Period covered	Release date	Period covered	MLR table number
Employment situation	August 6	July	September 3	August	1–11
Producer Price Index	August 13	July	September 10	August	23–27
Employment Cost Index	August 19	2nd quarter	....	....	32–34
Consumer Price Index	August 24	July	September 23	August	19–22
Real Earnings	August 24	July	September 23	August	12–17
Productivity and costs:					
Nonfinancial corporations	August 26	2nd quarter	....	....	28–31

EMPLOYMENT DATA FROM THE HOUSEHOLD SURVEY

EMPLOYMENT DATA in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 60,000 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

Definitions

Employed persons are (1) those who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work because they were on layoff or waiting to start new jobs within the next 30 days are also counted among the unemployed. The **unemployment rate** represents the number unemployed as a percent of the civilian labor force.

The **civilian labor force** consists of all employed or unemployed persons in the civilian noninstitutional population; the **total labor force** includes military personnel. Persons **not in the labor force** are those not classified as employed or unemployed; this group includes persons retired, those engaged in their own housework, those not working while attending school, those unable to work because of long-term illness, those discouraged from seeking work because of personal or job market factors, and those who are voluntarily idle. The **noninstitutional population** comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy.

Full-time workers are those employed at least 35 hours a week; **part-time workers** are those who work fewer hours. Workers on part-time schedules for economic reasons (such as slack work, terminating or starting a job during the week, material shortages, or inability to find full-time work) are among those counted as being on full-time status, under the assumption that they would be working full time if conditions permitted. The survey classifies unemployed persons in full-time or part-time status by their reported preferences for full-time or part-time work.

Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the preceding years. These adjustments affect the comparability of historical data presented in table 1. A description of these adjustments and their effect on the various data series appear in the Explanatory Notes of *Employment and Earnings*.

Data in tables 2-7 are seasonally adjusted, based on the seasonal experience through December 1981.

1. Employment status of the noninstitutional population, 16 years and over, selected years, 1950-81

[Numbers in thousands]

Year	Total non-institutional population	Total labor force		Civilian labor force						Not in labor force

EMPLOYMENT, HOURS, AND EARNINGS DATA FROM ESTABLISHMENT SURVEYS

EMPLOYMENT, HOURS, AND EARNINGS DATA in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by 177,000 establishments representing all industries except agriculture. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

Definitions

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12th of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in manufacturing include blue-collar worker supervisors and all nonsupervisory workers closely associated with production operations. Those workers mentioned in tables 12–17 include production workers in manufacturing and mining; construction workers in construction; and nonsupervisory workers in transportation and public utilities; in wholesale and retail trade; in finance, insurance, and real estate; and in services industries. These groups account for about four-fifths of the total employment on private nonagricultural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. **Real earnings** are earnings adjusted to reflect the effects of changes in consumer prices. The deflator for this series is derived from the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W). The **Hourly Earnings Index** is calculated from average hourly earnings data adjusted to exclude the effects of two types of changes that are unrelated to underlying wage-rate developments: fluctuations in overtime premiums in manufacturing (the only sector for which overtime data are available) and the effects of changes and seasonal factors in the proportion of workers in high-wage and low-wage industries.

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received and are different from standard or scheduled hours. **Overtime hours** represent the portion of gross average weekly hours which were in excess of regular hours and for which overtime premiums were paid.

Notes on the data

Establishment data collected by the Bureau of Labor Statistics are periodically adjusted to comprehensive counts of employment (called "benchmarks"). The latest complete adjustment was made with the release of May 1982 data, published in the July 1982 issue of the *Review*. Consequently, data published in the *Review* prior to that issue are not necessarily comparable to current data. Complete comparable historical unadjusted and seasonally adjusted data are published in a Supplement to Employment and Earnings (unadjusted data from April 1977 through February 1982 and seasonally adjusted data from January 1974 through February 1982) and in *Employment and Earnings, United States, 1909–78*, BLS Bulletin 1312–11 (for prior periods).

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20. See also *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976).

8. Employment by industry, selected years, 1950–81

[Nonagricultural payroll data, in thousands]

Year	Total	Mining	Construction	Manufacturing	Transportation and public utilities	Wholesale and retail trade	Wholesale trade	Retail trade	Finance, insurance, and real estate	Services	Government		
											Total	Federal	State and local
1950	45,197	901	2,364	15,241	4,034	9,386	2,635	6,751	1,888	5,357	6,026	1,928	4,098

NOTE: The industry divisions of mining; construction; tobacco manufactures (a major manufacturing group, nondurable goods); transportation and public utilities; and finance, insurance, and real estate are no longer shown. This is because the seasonal component in these is small relative to the trend-cycle, or irregular components, or both, and consequently cannot be precisely separated.

UNEMPLOYMENT INSURANCE DATA

NATIONAL UNEMPLOYMENT INSURANCE DATA are compiled monthly by the Employment and Training Administration of the U.S. Department of Labor from monthly reports of unemployment insurance activity prepared by State agencies. Railroad unemployment insurance data are prepared by the U.S. Railroad Retirement Board.

Definitions

Data for **all programs** represent an unduplicated count of insured unemployment under State programs, Unemployment Compensation for Ex-Servicemen, and Unemployment Compensation for Federal Employees, and the Railroad Insurance Act.

Under both State and Federal unemployment insurance programs for civilian employees, insured workers must report the completion of at least 1 week of unemployment before they are defined as unemployed. Persons not covered by unemployment insurance (about 10 percent of the labor force) and those who have exhausted or not yet earned benefit rights are excluded from the scope of the survey. **Initial claims** are notices filed by persons in unemployment insurance programs to indicate they are out of work and wish to begin receiving compensation. A claimant who continued to be unemployed a full week is then counted in the insured unemployment figure. The **rate of insured unemployment** expresses the number of insured unemployed as a percent of the average insured employment in a 12-month period.

An **application** for benefits is filed by a railroad worker at the beginning of his first period of unemployment in a benefit year; no application is required for subsequent periods in the same year. **Number of payments** are payments made in 14-day registration periods. The **average amount of benefit payment** is an average for all compensable periods, not adjusted for recovery of overpayments or settlement of underpayments. However, **total benefits paid** have been adjusted.

18. Unemployment insurance and employment service operations

[All items except average benefits amounts are in thousands]

[1] Initial claims and State insured unemployment include data under the program for Puerto Rican sugarcane workers.

[2] Excludes transition claims under State programs.

[3] Excludes data on claims and payments made jointly with other programs.

[4] Excludes data on claims and payments made jointly with State programs.

[5] Cumulative total for fiscal year (October 1-September 30). Data computed quarterly.

NOTE: Data for Puerto Rico and the Virgin Islands included. Dashes indicate data not available.

r = revised.

PRICE DATA

PRICE DATA are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base period (1967 = 100, unless otherwise noted).

Definitions

The **Consumer Price Index** is a monthly statistical measure of the average change in prices in a fixed market basket of goods and services. Effective with the January 1978 index, the Bureau of Labor Statistics began publishing CPI's for two groups of the population. One index, a new CPI for All Urban Consumers, covers 80 percent of the total noninstitutional population; and the other index, a revised CPI for Urban Wage Earners and Clerical Workers, covers about half the new index population. The All Urban Consumers index includes, in addition to wage earners and clerical workers, professional, managerial, and technical workers, the self-employed, short-term workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctor's and dentist's fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items is kept essentially unchanged between major revisions so that only price changes will be measured. Prices are collected from over 18,000 tenants, 24,000 retail establishments, and 18,000 housing units for property taxes in 85 urban areas across the country. All taxes directly associated with the purchase and use of items are included in the index. Because the CPI's are based on the expenditures of two population groups in 1972–73, they may not accurately reflect the experience of individual families and single persons with different buying habits.

Though the CPI is often called the "Cost-of-Living Index," it measures only price change, which is just one of several important factors affecting living costs. Area indexes do not measure differences in the level of prices among cities. They only measure the average change in prices for each area since the base period.

Producer Price Indexes measure average changes in prices received in primary markets of the United States by producers of commodities in all stages of processing. The sample used for calculating these indexes contains about 2,800 commodities and about 10,000 quotations per month selected to represent the movement of prices of all commodities produced in the manufacturing, agriculture, forestry, fishing, mining, gas and electricity, and public utilities sectors. The universe includes all commodities produced or imported for sale in commercial transactions in primary markets in the United States.

Producer Price Indexes can be organized by stage of processing or by commodity. The stage of processing structure organizes products by degree of fabrication (that is, finished goods, intermediate or semifinished goods, and crude materials). The commodity structure organizes products by similarity of end-use or material composition.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States, from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

In calculating Producer Price Indexes, price changes for the various commodities are averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1972. The detailed data are aggregated to obtain indexes for stage of processing groupings, commodity groupings, durability of product groupings, and a number of special composite groupings.

Price indexes for the output of selected SIC industries measure average price changes in commodities produced by particular industries, as defined in the *Standard Industrial Classification Manual 1972* (Washington, U.S. Office of Management and Budget, 1972). These indexes are derived from several price series, combined to match the economic activity of the specified industry and weighted by the value of shipments in the industry. They use data from comprehensive industrial censuses conducted by the U.S. Bureau of the Census and the U.S. Department of Agriculture.

Notes on the data

Beginning with the May 1978 issue of the *Review*, regional CPI's cross classified by population size, were introduced. These indexes will enable users in local areas for which an index is not published to get a better approximation of the CPI for their area by using the appropriate population size class measure for their region. The cross-classified indexes will be published bimonthly. (See table 21.)

For further details about the new and the revised indexes and a comparison of various aspects of these indexes with the old unrevised CPI, see *Facts About the Revised Consumer Price Index*, a pamphlet in the Consumer Price Index Revision 1978 series. See also *The Consumer Price Index: Concepts and Content Over the Years*, Report 517, revised edition (Bureau of Labor Statistics, May 1978).

For interarea comparisons of living costs at three hypothetical standards of living, see the family budget data published in the *Handbook of Labor Statistics, 1977*, Bulletin 1966 (Bureau of Labor Statistics, 1977), tables 122–133. Additional data and analysis on price changes are provided in the *CPI Detailed Report* and *Producer Prices and Price Indexes*, both monthly publications of the Bureau.

As of January 1976, the Wholesale Price Index (as it was then called) incorporated a revised weighting structure reflecting 1972 values of shipments. From January 1967 through December 1975, 1963 values of shipments were used as weights.

For a discussion of the general method of computing consumer, producer, and industry price indexes, see *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976), chapters 13–15. See also John F. Early, "Improving the measurement of producer price change," *Monthly Labor Review*, April 1978, pp. 7–15. For industry prices, see also Bennett R. Moss, "Industry and Sector Price Indexes," *Monthly Labor Review*, August 1965, pp. 974–82.

[1] Data for February 1982 have been revised to reflect the availability of late reports and corrections by respondents. All data are subject to revision 4 months after original publication.

[2] Prices for natural gas are lagged 1 month.

[3] Includes only domestic production.

[4] Most prices for refined petroleum products are lagged 1 month.

[5] Some prices for industrial chemicals are lagged 1 month.

[6] Not available.

r = revised.

25. Producer Price Indexes, for special commodity groupings

r = revised.

PRODUCTIVITY DATA

PRODUCTIVITY DATA are compiled by the Bureau of Labor Statistics from establishment data and from estimates of compensation and output supplied by the U.S. Department of Commerce and the Federal Reserve Board.

Definitions

Output is the constant dollar gross domestic product produced in a given period. Indexes of **output per hour of labor input**, or labor productivity, measure the value of goods and services produced per hour of labor. **Compensation per hour** includes wages and salaries of employees plus employers' contributions for social insurance and private benefit plans. The data also include an estimate of wages, salaries, and supplementary payments for the self-employed, except for nonfinancial corporations, in which there are no self-employed. **Real compensation per hour** is compensation per hour adjusted by the Consumer Price Index for All Urban Consumers.

Unit labor cost measures the labor compensation cost required to produce one unit of output and is derived by dividing compensation by output. **Unit nonlabor payments** include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from the current dollar gross domestic product and dividing by output. In these tables, **unit nonlabor costs** contain all the components of unit nonlabor payments except unit profits. **Unit profits** include corporate profits and inventory valuation adjustments per unit of output.

The **implicit price deflator** is derived by dividing the current dollar estimate of gross product by the constant dollar estimate, making the deflator, in effect, a price index for gross product of the sector reported.

The use of the term "man hours" to identify the labor component of productivity and costs, in tables 28 through 31, has been discontinued. **Hours of all persons** is now used to describe the labor input of payroll workers, self-employed persons, and unpaid family workers. **Output per all-employee hour** is now used to describe labor productivity in nonfinancial corporations where there are no self-employed.

Notes on the data

In the private business sector and the nonfarm business sector, the basis for the output measure employed in the computation of output per hour is Gross Domestic Product rather than Gross National Product. Computation of hours includes estimates of nonfarm and farm proprietor hours.

Output data are supplied by the Bureau of Economic Analysis, U.S. Department of Commerce, and the Federal Reserve Board. Quarterly manufacturing output indexes are adjusted by the Bureau of Labor Statistics to annual estimates of output (gross product originating) from the Bureau of Economic Analysis. Compensation and hours data are from the Bureau of Economic Analysis and the Bureau of Labor Statistics.

Beginning with the September 1976 issue of the *Review*, the productivity tables were revised to reflect changeover to the new series — private business sector and nonfarm business sector — which differ from the previously published total private economy and nonfarm sector in that output imputed for owner-occupied dwellings and the household and institutions sectors, as well as the statistical discrepancy, are omitted. For a detailed explanation, see J. R. Norsworthy and L. J. Fulco, "New sector definitions for productivity series," *Monthly Labor Review*, October 1976, pages 40–42.

WAGE AND COMPENSATION DATA

Data for the Employment Cost Index are reported to the Bureau of Labor Statistics by a sample of 2,000 private nonfarm establishments and 750 State and local government units selected to represent total employment in those sectors. On average, each reporting unit provides wage and compensation information on five well-specified occupations.

Data on negotiated wage and benefit changes are obtained from contracts on file at the Bureau, direct contact with the parties, and secondary sources.

Definitions

The **Employment Cost Index** (ECI) is a quarterly measure of the average change in the cost of employing labor. The rate of total compensation, which comprises wages, salaries, and employer costs for employee benefits, is collected for workers performing specified tasks. Employment in each occupation is held constant over time for all series produced in the ECI, except those by region, bargaining status, and area. As a consequence, only changes in compensation are measured. Industry and occupational employment data from the 1970 Census of Population are used in deriving constant weights for the ECI. While holding total industry and occupational employment fixed, in the estimation of indexes by region, bargaining status, and area, the employment in those measures is allowed to vary over time in accord with changes in the sample. The rate of change (in percent) is available for wages and salaries, as well as for total compensation. Data are collected for the pay period including the 12th day of the survey months of March, June, September, and December. The statistics are neither annualized nor adjusted for seasonal influence.

Wages and salaries consist of earnings before payroll deductions, excluding premium pay for overtime, work on weekends and holidays, and shift differentials. Production bonuses, incentive earnings, commissions, and cost-of-living adjustments are included; nonproduction bonuses are included with other supplemental pay items in the benefits category; and payments-in-kind, free room and board, and tips are excluded. *Benefits* include supplemental pay, insurance, retirement and savings plans, and hours-related and legally required benefits.

Data on negotiated wage changes apply to private nonfarm industry collective bargaining agreements covering 1,000 workers or more. Data on compensation changes apply only to those agreements covering 5,000 workers or more. *First-year* wage or compensation changes refer to average negotiated changes for workers covered by settlements reached in the period and implemented within the first 12 months after the effective date of the agreement. *Changes over the life of the agreement* refer to all adjustments specified in the contract, expressed as an average annual rate. These measures exclude wage changes that may occur under cost-of-living adjustment clauses, that are triggered by movements in the Consumer Price Index. *Wage-rate changes* are expressed as a percent of straight-time hourly earnings; *compensation changes* are expressed as a percent of total wages and benefits.

Effective wage adjustments reflect all negotiated changes implemented in the reference period, regardless of the settlement date. They include changes from settlements reached during the period, changes deferred from contracts negotiated in an earlier period, and cost-of-living adjustments. The data also reflect contracts providing for no wage adjustment in the period. Effective adjustments and each of their components are prorated over all workers in bargaining units with at least 1,000 workers.

Notes on the data

The Employment Cost Index data series began in the fourth quarter of 1975, with the quarterly percent change in wages and salaries in the private nonfarm sector. Data on employer costs for employee benefits were included in 1980, to produce a measure of the percent change in employers' cost for employees' total compensation. State and local government units were added to the ECI coverage in 1981, providing a measure of total compensation change in the civilian nonfarm economy.

Data for the broad white-collar, blue-collar, and service worker groups, and the manufacturing, nonmanufacturing, and service industry groups are presented in the ECI. Additional occupation and industry detail are provided for the wages and salaries component of total compensation in the private nonfarm sector. For State and local government units, additional industry detail is shown for both total compensation and its wages and salaries component.

Historical indexes (June 1981 = 100) of the quarterly rates of changes presented in the ECI are also available.

For a more detailed discussion of the ECI, see chapter 25, "The Employment Cost Index," of the BLS *Handbook of Methods* (Bulletin 1910), and the *Monthly Labor Review* articles: "Employment Cost Index: a measure of change in the 'price of labor,'" July 1975; "How benefits will be incorporated into the Employment Cost Index," January 1978; and "The Employment Cost Index: recent trends and expansion," May 1982.

Additional data for the ECI and other measures of wage and compensation changes appear in *Current Wage Developments*, a monthly periodical of the Bureau.

Nonmanufacturing (excluding construction):														
First year of contract	8.0	8.0	7.6	9.5	9.8	9.4	10.3	9.5	8.2	8.0	11.8	8.6	9.6	1.8
Annual rate over life of contract	5.9	6.5	6.2	6.6	7.3	7.6	8.5	5.9	6.8	7.3	9.1	7.2	5.6	1.4
Construction:														
First year of contract	6.3	6.5	8.8	13.6	13.5	10.8	12.2	15.4	14.3	11.4	12.9	16.4	11.4	9.3
Annual rate over life of contract	6.3	6.2	8.3	11.5	11.3	9.1	10.4	13.0	12.0	10.3	11.1	12.4	11.7	8.9

36. Effective wage adjustments in collective bargaining units covering 1,000 workers or more, 1977 to date

Measure	Year					Year and quarter								
						1980				1981				1982^p
	1977	1978	1979	1980	1981	I	II	III	IV	I	II	III	IV	I
Average percent adjustment (including no change):														
All industries	8.0	8.2	9.1	9.9	9.5	1.6	3.3	3.5	1.3	1.7	3.2	3.3	1.5	.9
Manufacturing	8.4	8.6	9.6	10.2	9.4	2.0	3.4	2.9	1.7	2.3	2.4	3.1	1.9	.8
Nonmanufacturing	7.6	7.9	8.8	9.7	9.5	1.3	3.2	4.0	1.1	1.2	3.8	3.4	1.1	1.0
From settlements reached in period	3.0	2.0	3.0	3.6	2.5	.4	1.0	1.7	.5	.4	1.1	.5	.4	.1
Deferred from settlements reached in earlier period	3.2	3.7	3.0	3.5	3.8	.5	1.4	1.2	.3	.5	1.4	1.5	.4	.5
From cost-of-living clauses	1.7	2.4	3.1	2.8	3.2	.7	.8	.7	.6	.7	.7	1.2	.6	.2
Total number of workers receiving wage change (in thousands)[1]	—	—	—	—	8,648	—	—	—	—	3,855	4,701	4,384	3,225	2,713
From settlements reached in period	—	—	—	—	2,270	—	—	—	—	579	909	540	604	153
Deferred from settlements reached in earlier period	—	—	—	—	6,267	—	—	—	—	988	2,055	3,023	882	1,033
From cost-of-living clauses	—	—	—	—	4,593	—	—	—	—	2,630	2,880	2,934	2,179	1,750
Number of workers receiving no adjustments (in thousands)	—	—	—	—	145	—	—	—	—	4,937	4,092	4,428	5,588	6,176

[1] The total number of workers who received adjustments does not equal the sum of workers that received each type of adjustment, because some workers received more than one type of adjustment during the period.

WORK STOPPAGE DATA

Work stoppages include all known strikes or lockouts involving 1,000 workers or more and lasting a full shift or longer. Data are based largely on newspaper accounts and cover all workers idle one shift or more in establishments directly involved in a stoppage. They do not measure the indirect or secondary effect on other establishments whose employees are idle owing to material or service shortages.

Estimates of days idle as a percent of estimated working time measures only the impact of larger strikes (1,000 workers or more). Formerly, these estimates measured the impact of strikes involving 6 workers or more; that is, the impact of virtually *all* strikes. Due to budget stringencies, collection of data on strikes involving 6 workers or more was discontinued with the December 1981 data.

37. Work stoppages involving 1,000 workers or more, 1947 to date

Month and year		Number of stoppages		Workers involved		Days idle	
		Beginning in month or year	In effect during month or year	Beginning in month or year (in thousands)	In effect during month (in thousands)	Number (in thousands)	Percent of estimated working time

SALES PUBLICATIONS

BLS Bulletins

Bargaining Calendar, 1982. Bulletin 2127, 63 pp., $4.50 (GPO Stock No. 029-001-02698-6). Presents information on anticipated union adjustments for 1982. The information—identified by company and union—includes major situations in which contracts expire, deferred wage increases come due, escalator clauses are reviewed, and contracts are reopened.

BLS Economic Growth Model System Used for Projections to 1990. Bulletin 2112, 108 pp., $5.50 (GPO Stock No. 029-001-02705-2). Describes the current Economic Growth model which was used to develop the revised 1990 industry and occupational employment projections. Intended for analysts who desire detailed information on the BLS projection methods, models, and techniques.

Major Collective Bargaining Agreements: Union Security and Dues Checkoff Provisions. Bulletin 1425-21, 75 pp., $4.75 (GPO Stock No. 029-001-02707-9). The 21st and last in a series of BLS studies, this bulletin provides information about two important issues in collective bargaining: The protection of a union's status by some type of union security provision and the collection of union dues by a dues checkoff arrangement.

Occupational Injuries and Illnesses in the United States by Industry, 1980. Bulletin 2130, 48 pp., $3.25 (GPO Stock No. 029-001-02706-1). Contains 1979 and 1980 data by industry on occupational injuries, illnesses, and fatalities in private, nonfarm establishments.

Occupational Outlook Handbook, 1982-83 Edition. Bulletin 2200, 484 pp., $9, softcover edition; $13, hardcover edition (GPO Stock No. 029-001-02651-0). An encyclopedia of careers covering more than 250 occupations. For each of these occupations information is included on what the work is like, job prospects through the 1980's, level and places of employment, educational and training requirements, advancement possibilities, related occupations, and where to find additional information.

Area Wage Survey Bulletins

Washington, D.C.-Maryland-Virginia, Metropolitan Area, March 1982. Bulletin 3015-8.

The annual series of 70 area wage survey bulletins is available by subscription for $90 per year.

Periodicals

CPI Detailed Report, April. Comprehensive report on consumer price movements, including statistical tables and technical notes. 109 pp., $3.50 ($20 per year).

Current Wage Developments, June. Monthly report on employee wage and benefit changes; collective bargaining settlements; and special wage trends. 62 pp., $2.50 ($14 per year).

Employment and Earnings, June. Report on national, State, and area employment; unemployment; hourly and weekly earnings; and hours of work for May. 152 pp., $3.75 ($31 per year). Special feature of this issue: Annual averages for unemployment in States and areas; Establishment data adjusted to new benchmarks.

Occupational Outlook Quarterly, Summer 1982, supplement to the Occupational Outlook Handbook featuring guidance information on selected careers each quarter, 40 pp.,$2.75 ($8 per year).

Articles: The Job Outlook for College Graduates During the 1980's; The Class of '77 One Year After Graduation; Career Information: What's Available in Schools? You're a What? Puppeteer.

Producer Prices and Price Indexes, Data for April 1982. Monthly report on producer price movements. Text, tables, and technical notes. 116 pp., $3.25 ($20 per year).

Microfiche

Gross Flow Data From the Current Population Survey, 1970-80. Provides unpublished data on movements between various labor force classifications. Available only from the National Technical Information Service, U.S. Department of Commerce, 5285 Port Royal Road, Springfield, Va. 22151. Order No. PB82-174327.

Employment and Unemployment in States and Local Areas, January-June 1981. Provides provisional monthly estimates of the labor force, employment and unemployment for States, labor market areas, counties, and cities of 25,000 or more inhabitants. These estimates are used in the administration of Federal economic assistance programs.

Mailgram Service

Consumer price index data summary by mailgram within 24 hours of the CPI release. Provides unadjusted and seasonally adjusted U.S. City Average data for All Urban Consumers (CPI-U) and for Urban Wage Earners and Clerical Workers (CPI-W). (NTISUB/158). $125 in contiguous United States.

FREE PUBLICATIONS

BLS Reports

Evaluating Your Firm's Injury and Illness Record, 1980: Transportation and Public Utilities Industries. Report 662, 11 pp. Wholesale and Retail Trade Industries. Report 661, 13 pp. These reports provide a means of comparing a firm's safety record with the record of other firms of similar size and with the industry as a whole. They present tabulations of occupational injury and illness incidence rates for the subject industry by employment size and quartile distribution.

U.S. Department of State Indexes of Living Costs Abroad and Quarters Allowances, April 1982. Report 666, 6 pp. Beginning with the next issue, this quarterly publication will be for sale by the Superintendent of Documents. (Subscription—$6.50, single copy—$1.75.)

Employment in Perspective: Minority Workers, First Quarter 1982, Report 667. 3 pp. Focuses on some of the available labor force data for black, and Hispanic workers by family type and family relationship in 1981.

Evaluating Your Firm's Injury and Illness Record, 1980:
Construction Industries, May 1982. Report 659. 9 pp.
Manufacturing Industries, May 1982. Report 660. 31 pp.

MONTHLY LABOR REVIEW

Labor Month In Review

JOBS FOR COLLEGE GRADS. The Bureau of Labor Statistics published a report on the job outlook for college graduates in the 1980's. Here are excerpts from the article by Jon Sargent in the summer issue of *Occupational Outlook Quarterly*.

Supply. The number of bachelor's degrees awarded increased from 502,000 during the 1964-65 school year to 929,000 during the 1979-80 school year, an increase of more than 85 percent. The number of bachelor's degrees awarded annually is expected to increase slowly during the early 1980's, but as the baby-boom cohort passes out of the typical ages of college attendance, the number of degrees granted annually is expected to fall. This decline should be softened, however, by continued increases in college attendance by older workers. By 1990, the number of bachelor's degrees awarded will settle back to about the 1980 level. On the average, however, slightly more bachelor's degrees will be awarded annually during the 1980-90 period than in 1980.

Women college graduates were increasingly likely to be members of the labor force during the 1970's. The proportion of women with college degrees who were either employed or looking for work climbed from 59.6 percent in 1970 to 68.4 percent in 1980, continuing a long-term trend. This increase primarily stemmed from the growing tendency of married women graduates between the ages of 25 and 44 to combine work with family responsibilities. The proportion of this group in the labor force grew from 49 percent in 1970 to 69 percent in 1980; the proportions of other women graduates in the labor force increased only slightly over the period. The growing labor force commitment of women college graduates increased the impact of the baby-boom generation on the labor force. Their numbers were unprecedented, as was the proportion who sought jobs.

During the 1980's, the upward trend in the labor force participation rate of women is expected to continue, offsetting somewhat the impact of fewer people entering their twenties. Labor force growth will nevertheless slow. Women will account for about two-thirds of the labor force growth between 1980 and 1990.

Demand. During the 1970's, employment in professional and technical, managerial, and nonretail sales jobs—occupations generally requiring substantial proportions of workers with a degree—increased 40 percent, compared to about 28-percent growth for all workers. Between 1980 and 1990, employment in these occupations is projected to grow more slowly. They are expected to increase between 18 and 25 percent, depending on varying assumptions about growth in the economy, about as fast as the average for all occupations in the 1980's.

Educational upgrading was projected to occur in professional and technical, managerial and administrative, and nonretail sales occupations, continuing the trend toward greater complexity and skill requirements for many of these jobs, as well as employers' responses to a greater supply. A constant, but small, proportion of the jobs in other occupations was projected to require a college degree.

Outlook. A surplus of between 2 and 3 million college graduates is expected to enter the labor force during the 1980's. If the economy grows as slowly as it did during the 1970's, the surplus would be the higher figure, an average annual surplus of about 300,000 college graduates—about 1 graduate in 5, just as in the 1970's. If the economy grows more rapidly than it did in the 1970's, the average surplus would be about 200,000 college graduates—about 1 in 7—each year.

Even with more rapid growth, however, the job market experienced by college graduates in the 1980's is unlikely to be more favorable than in the 1970's. In 1980, a surplus of college graduates estimated at 3.8 million was already in the labor force, either employed in jobs that did not require their level of education or unemployed. Of course, many of these have since begun satisfying careers in occupations that do not require 4 years of college education. Others, however, can be expected to compete for jobs that more fully utilize their education. The job market will be more competitive to the extent that this pool of underemployed 1970's entrants competes with 1980's entrants for job openings requiring a college degree.

Like college graduates in the 1970's, future college graduates cannot be assured that they will find jobs in the occupations of their choice. Many may experience periods of unemployment, have to relocate to other areas of the country, or job-hop before finding one that satisfies them. As in the 1970's, some may have to compete with nongraduates for the more desirable jobs not previously filled by graduates, but in many cases, their additional education will prove to be an advantage. Even though a college degree may not be required, many employers prefer to hire the best educated candidate who is qualified for a job. In many cases, a college graduate will also have an advantage in gaining promotion in non-college careers over those without degrees. Many graduates who are forced to start work in jobs for which they are overqualified nevertheless may gain useful experience that will be an advantage in competing later for more challenging jobs.

The summer *Occupational Outlook Quarterly* is available from BLS regional offices (see inside front cover) at $2.75 per copy. □

Tracking job growth in private industry

Small, young firms are very important to the process of job generation, according to three recent studies of the behavior of individual employers

RICHARD GREENE

The job generation process has been one of the most heavily debated public policy issues of recent years. Governments at the Federal, State, and local levels have invested heavily in programs designed to create jobs—including urban and general economic development plans, tax credits and incentives, and public sector employment programs—and to improve the ability of individuals to compete effectively in the labor market by providing basic education and training in new and expanding fields. Much current interest centers on the problem of matching unemployed workers from declining industries to opportunities in areas with expanding manpower needs, such as high technology and defense-related activities. An interesting legislative approach, the Small Business Research Innovation Act,[1] is a proposal to set aside Federal research money for small businesses in order to spur technological innovation and create new jobs. The success of efforts to increase employment through economic policy hinges on the ability to understand the job creation process, identify the job creators, and develop policy initiatives that enhance their potential.

Aggregate data on employment levels and changes by industry and geographic area provide meaningful information on overall labor market trends, but are limited for the study of job creation in that they essentially portray net results. The employment changes reported monthly by the Bureau of Labor Statistics are the result of many thousands of production-function decisions made by individual employers, based on the relationship between their particular output and labor requirements. To understand the process of job creation, it is necessary to go beyond the aggregated data, and examine the multitude of business decisions at the establishment level.

This article summarizes the findings and methodology of some of the recent innovative labor market studies of this type in the private sector. Emphasis is placed on the microdata-based study of the job creation process under the direction of David Birch, director of the Massachusetts Institute of Technology (MIT) Program on Neighborhood and Regional Change.[2] Similar studies by the Institute of Urban and Regional Development of the University of California at Berkeley, under the direction of Michael B. Teitz,[3] and by the Brookings Institution[4] will also be summarized. These efforts, with appropriate refinement and extension, have the potential to improve significantly the body of labor market information used to guide the development of economic policy in this country.

The MIT program

David Birch of MIT has developed a theoretically simple approach to the analysis of the job creation process, based on the employment histories of nearly 6 million individual employers. Each firm in the MIT data base is characterized on the basis of location, size of employment, parent company affiliation, industry, and

---

Richard Greene, formerly with the Office of Employment Structure and Trends, Bureau of Labor Statistics, is now an economist with the U.S. Department of State.

age. By comparing changes in these characteristics over time, Birch was able to trace in some detail the path of economic transformation of individual firms. By aggregating the changes in these characteristics for all establishments in a given sector or area, he was able to describe the overall labor market changes in that sector or area and, most importantly, how these changes occurred.

Some highlights:

- Overall employment change in a private-sector labor market is the result of:
  - —Births of new firms
  - —Expansions of existing firms
  - —Firms going out of business
  - —Firms reducing their work forces
  - —Firms moving their places of business
- The sum of the flows causing job losses (concerns going out of business or reducing their work forces) is nearly the same in all areas. The job loss rate averages about 8 percent annually.
- The job loss rate is quite high. Every area loses about 50 percent of its jobs every 5 years.
- Differences in net employment growth are largely the result of differences in the rates at which job losses are replaced. This replacement rate varies greatly from area to area.
- There are significant differences in the rates at which net new jobs are generated in various parts of the country.
- The establishments generating new jobs tend to be:
  - —*Small.* About two-thirds of all net new jobs between 1969 and 1976 were created by firms with 20 or fewer employees.
  - —*Young.* About 80 percent of all "replacement" jobs between 1969 and 1976 were generated by establishments in business 4 years or less.
  - —*Volatile.* Job generators tend to move through periods of expansion and retrenchment as they grow.
- Virtually none of the difference in the job generation capability of labor markets is due to firms moving their staffs and physical plants to different areas. Few businesses relocate, and when they do, they move short distances.

The MIT studies are basically a longitudinal analysis of the individual establishment data collected by Dun and Bradstreet (D&B). The D&B files are based on establishment reports of all businesses with commercial credit ratings. The data are used by D&B for its credit rating operation, but are commercially available to other enterprises for market research, mailing list preparation, billing, and associated activities. D&B collects many useful economic observations, including the year the establishment started, location, employment, sales, major industry, and any branch or subsidiary relationships. The information is collected by a full-time staff of 1,700 reporters, assisted by 500 part-time employees.

Files containing all D&B establishments for the years 1969, 1972, 1974, and 1976 were used by the MIT project group to build a data base. A micro history of each employer was developed by matching the firms from year to year by the unique identifying number assigned by D&B. (That number stays the same as long as the establishment is in the file, regardless of any change in location, size, or industry.) This economic history then allows a detailed analysis of changes in employment, location, corporate affiliation, and life cycles. When the data are aggregated on the basis of various characteristics, it is possible to identify the types of firms that created the greatest number of jobs.

Any review of the MIT findings must be tempered by an understanding of both the nature of the D&B files and the techniques used by MIT staff to build the data base. It should be emphasized that the D&B file was not designed as a time series or census of activity in a particular area or industry. As a result, a number of problems arise when the data are used for longitudinal analysis.

A major problem with the MIT model is that births of firms tend to be underreported for the years covered by the study. D&B makes no effort to enter historical data for each newly reported firm in its files. This means, for example, that a firm appearing on the 1975 D&B file for the first time might actually have started operations in 1972. Consequently, the MIT model treats any newly reported firm which is known to have been established before the period being studied as a new listing, rather than a birth. These new listings are excluded from any aggregate analysis of economic change during the current and previous periods. They are, however, incorporated into the base-period employment for the analysis of future periods.

A second problem is attributable to the 2- and 3-year intervals between the observations forming the model's history. A large number of firms, particularly smaller firms, are formed and go out of business within a year or two. Because the MIT studies use data gathered at intervals greater than the life cycles of these firms, any aggregate measure of employment change will understate the actual number of business births and deaths occurring during an interval.

A third problem involves D&B's treatment of branch establishments. Employment in branches is often understated or even unreported because branches do not usually receive separate credit ratings. And, because D&B does not report the year that branch offices are started, the MIT model assumes that all new branch listings are births. However, because a 1976 D&B study of 1,000 firms indicated that nondisaggregated headquarters employed only 16 percent of all employees in headquarters and branch establishments, the MIT team did not consider the nondisaggregation of branch data to be a major problem.

The D&B file also has the same general problems of other large-scale employer data bases regarding geographical and industrial coding, clerical errors, and employer reporting mistakes. Errors of this type are extremely difficult to identify or measure without the use of costly employer validation visits. The MIT team developed an elaborate editing process which attempts to account for most of these deficiencies. However, an evaluation of the results of the MIT studies should take into account the nature of the D&B file and the problems inherent in constructing a history of nearly 6 million employers.

Components of change. The extent to which an area's job pool expands or contracts over time depends on the balance between those changes increasing the job pool —business births, expansions, and inmigration—and those decreasing the job pool—business deaths, contractions, and outmigration. All of these events are occurring simultaneously in every labor market. For employment to increase over time, births, expansions, and inmigration must be greater than those components causing employment decreases.

The following tabulation summarizes the percentage employment changes resulting from the different components of employment change. Data are averaged for all States during three periods. (The MIT project also produced similar data by neighborhood, city, Standard Metropolitan Statistical Area, region, and for individual States.)

	1969–72	*1972–74*	*1974–76*
Births	5.6	5.5	6.7
Deaths	5.2	4.5	5.7
Expansions	4.7	5.3	4.4
Contractions	2.9	2.6	3.4
Inmigration	.1	.1	.1
Outmigration	.03	.05	.01

This tabulation reveals several important characteristics of the employment change process. As noted, relocation is not significant, contrary to popularly held opinions. At the city level, migration of firms becomes more important, but its net effect on total employment remains insignificant when compared to the other factors. When firms move, they usually move short distances, as from an inner city to a suburb. Most of the observed firm outmigrations during 1969–76 were from New York City and Washington, D.C., to the surrounding suburbs.

The rates of job loss from business deaths and contractions are roughly the same from year to year. The business death rates varied about 1 percent with the direction of the business cycle during the period of this study. This trend also holds at the State and city levels. The following tabulation compares the rates of employment loss and gain during the 1972–76 period for 10 metropolitan areas selected to demonstrate a variety of overall growth rates:

Area	*Percent gain*	*Percent loss*	*Overall percent change*
Houston	62.7	35.7	27.0
Charlotte	48.0	40.4	7.5
Dayton	36.4	31.4	5.1
Rochester	33.7	29.3	4.5
Boston	37.4	33.7	3.8
Baltimore	36.5	32.9	3.5
Hartford	36.6	35.5	1.1
Worcester	24.6	25.1	.5
New Haven	27.0	29.5	-2.6
Greenville	26.9	35.1	-8.4

Perhaps even more important than the relatively small range in employment loss rates is the fact that the job loss rates were generally greater in areas with the highest growth rates (that is, Houston and Charlotte). It is also interesting to note that the employment loss rate averages about 8 percent per year in most of the areas. Compounding that employment loss rate means that an area must replace about 50 percent of its jobs every 5 years to maintain its employment base.

Among the 10 metropolitan areas, the range of employment gain rates is almost 2½ times greater than the range of employment loss rates. The employment gain rates were, as might be expected, highest in the fast-growth areas. Generally, differences in employment growth rates are the result of variations in the employment gains from new firms starting up and existing firms expanding operations, rather than differences in employment losses resulting from layoffs, or from firms going out of business or migrating to other areas.

The Birch study indicates that an area must replace an average of 8 percent of its jobs every year to maintain a constant employment level. And, to expand its employment base, an area must obviously generate additional jobs. In Phoenix, for example, nonagricultural employment increased 2.9 percent, or from 613,000 to 631,000, in 1980. To attain that growth rate, the Phoenix economy actually had to generate approximately 66,700 jobs, of which almost 75 percent replaced job losses.

Firm size and location. Two-thirds of all net new jobs were created by firms with 20 employees or fewer, and about four-fifths were created by firms with 100 employees or fewer, according to the MIT model of 5.6 million businesses between 1969 and 1976. The results here are consistent with other research which found that,

Table 1. Percent of net new jobs created and percent of total employment by firm size and region, 1972–76

Region	Firm size: 20 or fewer workers	21 to 50 workers	51 to 100 workers	101 to 500 workers	More than 500 workers
Northeast:					
Percent of net jobs created	177.1	6.5	−17.4	−33.3	−32.9
Percent of total employment	21.7	12.8	10.5	23.4	31.7
North Central:					
Percent of net jobs created	67.2	12.0	5.2	3.1	12.4
Percent of total employment	20.5	12.7	10.2	22.9	33.8
South:					
Percent of net jobs created	53.5	11.2	5.5	9.4	20.4
Percent of total employment	22.0	12.6	10.0	23.1	32.3
West:					
Percent of net jobs created	59.5	11.6	6.3	9.3	13.3
Percent of total employment	23.3	13.6	10.8	22.2	30.0

Source: David Birch, *The Job Generation Process*, mimeo (MIT Program on Neighborhood and Regional Change, February 1979).

over the last 10 years, small businesses created 3 million jobs, while the 1,000 largest firms recorded virtually no net gains in employment.[5]

In 1976, small firms accounted for only about 24 percent of the private-sector employment in the country, while registering 66 percent of the employment growth. Firms with over 500 employees account for about 27 percent of employment but only 13.3 percent of job generation. Firms in the middle range generated the least employment growth. The relatively strong job generating capacity of small firms must be interpreted in relationship to the behavior of larger firms, for growth in their proportion of total employment may indicate either an increase in employment in small firms or a decrease in employment in larger firms.

Table 1 shows that another important pattern of job generation is that the slower growth areas rely more heavily on smaller businesses to generate new jobs; larger firms generate a greater percentage of net jobs in the faster growth areas. Across regional lines, small firms are the major creators of new jobs. Between 1972 and 1976, firms with 50 or fewer employees generated basically all net new jobs in the Northeast, almost 80 percent in the North Central, and about two-thirds of the new jobs in the South and West. The distribution of overall employment by size of firm was roughly the same from region to region, but there were wide disparities in the percentage of jobs generated by size class. In the Northeast, all but the small establishments were actually net job losers during 1972–76.

Age of firm. Another distinguishing characteristic of job generators is their youth. According to the MIT model, about 80 percent of the replacement jobs are created by establishments which have been operating less than 4 years. This proportion is remarkably similar among regions.

Years in business	Percent of jobs created: Northwest	North Central	South	West
Less than 4	75.5	80.8	80.4	80.9
5 to 8	10.4	8.4	9.9	8.8
9 to 12	7.5	6.0	5.1	5.5
13 or more	6.6	4.8	4.6	4.8

The correlation between age and employment growth was also found in a California study of additions to employer payroll during the 1976–77 period.[6] This study concluded that small firms less than a year old had much higher rates of payroll accession than other firms, accounting for 4.4 percent of total employment and more than 11 percent of the total payroll accessions.

The use of age of business as a variable to study employment growth patterns is a characteristic unique to the D&B files. No other major employer data base contains the year that a business was started. (The California study compared unemployment insurance employer records over 5 calendar quarters to identify new firms and to track their subsequent movements.)

Industry developments. As would be expected, service-producing industries generated most of the new jobs. In fact, the service sector was responsible for virtually all of the employment growth during the 1972–76 period, increasing its share of total nonfarm employment from 67.9 percent to 70.6 percent. (This employment shift to service industries is also reflected in aggregate BLS data, shown in table 2.) Manufacturing firms in the MIT model actually generated no net new jobs, although certain high-technology industries showed strong employment growth. Service industries kept employment bases rela-

Table 2. Employment of industry divisions characterized by large and by small establishments, and changes, 1974–80

Industry	Employment (in thousands): March 1980	March 1974	Change, 1974–80	Average size of establishment, 1980	Percentage of total growth	Percentage employment change
Total, private sector	73,720	63,089	10,631	17	100.0	16.9
Small-establishment industries:						
Trade	20,068	16,537	3,531	13	. . .	21.4
Finance, insurance, and real estate . . .	5,090	4,107	983	13	. . .	23.9
Services	17,636	13,191	4,445	13	. . .	33.7
Construction	4,087	3,878	209	18	. . .	5.4
Total	. . .	. . .	9,168	12	86.2	. . .
Large-establishment industries:						
Manufacturing	20,722	20,027	695	62	. . .	3.3
Mining	990	665	325	32	. . .	32.8
Transportation and public utilities	5,127	4,684	443	27	. . .	9.5
Total	. . .	. . .	1,463	49	13.8	. . .

Source: U.S. Bureau of Labor Statistics.

tively stable in many areas where manufacturing industries were incurring severe losses.

Job generation is a cheaper, simpler process in the less capital-intensive service industries. There are few barriers to entry by new firms in most of this sector. Because many of the industries provide "custom designed" products, their production tends to be quite labor-intensive. The demand for business, health, and personal services has risen dramatically and is reflected in the number of new jobs.

Corporate structure. Job creation patterns are strongly affected by the corporate structure of the generating firms. Job creation resulting from the birth of new establishments increasingly reflects the branching activities of existing firms. The share of employment created by branching activity increased from approximately 50 percent to over 70 percent in all regions between 1974 and 1976. However, after having established branches, corporations are less likely to expand them. The majority of expansion growth is accounted for by independent firms, that is, firms having no branches or subsidiaries. The following tabulation shows percentage employment gains by region and type of establishment during 1974–76:

	Births			
	Independent	*Headquarters*	*Subsidiary*	*Branch*
Northeast	23.6	2.0	1.4	72.0
North Central .	19.9	1.4	1.1	77.6
South	25.2	1.6	1.4	71.7
West	24.0	1.7	1.1	72.2

	Expansions			
	Independent	*Headquarters*	*Subsidiary*	*Branch*
Northeast	58.2	21.1	6.7	14.0
North Central .	54.5	20.9	5.0	19.6
South	54.2	17.4	5.7	22.7
West	56.9	22.2	4.6	16.3

Independent firms accounted for about 20 to 25 percent of the employment gained by births of new firms and 50 to 60 percent of the employment gained by expansion of existing firms between 1974 and 1976. Overall, independent firms accounted for about one-half of the total jobs created during the 1974–1976 period. These trends in job generation by corporate structure are quite consistent from region to region but do vary by industry. Independents play a more important role in trade and services—the growing sectors of the economy. Branching tends to be more important in manufacturing industries. It is also noteworthy that more than 65 percent of all manufacturing jobs generated in the South were in branches controlled by corporations headquartered in other parts of the country, mainly the Northeast and North Central sections. By 1976, branches accounted for roughly 40 percent of all job replacement activities in the South, and an even greater share in manufacturing.

The Brookings Microdata Project

The Brookings Institution used the United States Establishment and Enterprise Microdata files, developed by the U.S. Small Business Administration, to examine the components of employment change between 1978 and 1980. These files are basically updates of the D&B files used by Birch. The major conclusions from the Brookings project:

- Between 1978 and 1980, 55 percent of the net employment growth was in establishments with fewer than 20 employees. About 78 percent of the net 1978–80 growth was in establishments with under 100 workers.
- Approximately one half of this employment growth represents branching or establishment of subsidiaries by large firms.
- Small independent firms generate new jobs at a rate about equal to their proportion of total employment.
- The proportion of employment growth accounted for by these small firms increases in regions and industries with declining employment, and decreases in regions and industries with expanding employment.

The Brookings analysis of employment growth between 1978 and 1980 both differs from and confirms some of Birch's major hypotheses regarding the behavior of small business. Both studies confirm the turbulent job generating behavior of establishments with fewer than 100 employees. However, it should be noted that the studies differ as to how to classify small branches of larger firms. The Brookings project, for the most part, excludes these establishments from the discussion of small business behavior.

Like the MIT study, the Brookings project also emphasizes the importance of examining small business behavior relative to the performance of larger firms. Finally, the Brookings project introduces a more recent data source for the study of the job generation process—the 1978 and 1980 United States Establishment and Enterprise Microdata files.

The University of California study

The study by the University of California Institute of Urban and Regional Development used individual employer records from the mandatory unemployment insurance system to analyze the job generation process. The study, directed by Michael Teitz, was based on records for a sample of just over 25,000 California employers from the 1975–79 period. The Teitz study differed from the MIT project in terms of sample size, geographic coverage, reference period, and data source. However, the results are remarkably similar to those noted by Birch.

- During 1975–79, establishments with fewer than 20 employees accounted for 56 percent of the net gains in employment. (Birch estimated that such firms contributed about two-thirds of the net job gains.)
- Firms less than 2 years old accounted for a much greater share of the net employment growth than older firms.
- More than 90 percent of the net new jobs in the young, small firms were in the nonmanufacturing sector.
- Job losses resulting from layoffs and from firms going out of business or undergoing ownership changes varied by size class. Teitz found that at least 7 percent of jobs existing in companies with fewer than 10 workers at the beginning of their second year of business had disappeared by the third year. This is in line with Birch's estimated overall job loss rate of about 8 percent per year. In general, Teitz noted an even greater degree of volatility—alternating periods of expansion and retrenchment—in the job generation process than did Birch.

The Teitz study provides some other interesting observations on the job generation process. In particular, Teitz found that, while small new firms dominated the job creating process, most of the new employment growth was concentrated in a small percentage of these firms. He also concluded that, in the California manufacturing sector, larger firms are the major generators of net new jobs.

The Teitz study is important in several respects. First, it introduces another data source—the administrative records of the unemployment insurance system—which may be used to build a history of individual employers. While these data are affected by the same general types of problems faced by users of the D&B file, Teitz's discussion and treatment of these problems should help other analysts of the unemployment insurance micro data. Secondly, the study tends to confirm some of the provocative conclusions of the Birch study regarding the nature of the job generation process. Perhaps just as importantly, Teitz's study provides more documentation on how the quality of labor market information can be improved by examining the individual employer data. Finally, Teitz introduces an interesting concept regarding the concentration of employment growth in a relatively few small firms. Further study of this characterization of the job generation process should be an important part of any effort to develop improved job generation strategies.

The future of micro research

In coming years, at least three major sources of individual establishment data will be available to the policy analyst: the D&B data base; unemployment insurance records; and the U.S. Department of Commerce's Standard Statistical Establishment List. Each source has its respective strengths and limitations for breaking down and analyzing macro labor force movements. Each of these important data bases is the byproduct of an administrative record keeping system which was not designed for time series analysis. The characteristics of the D&B file, the basis for the MIT and Brookings studies, were described above in conjunction with the discussion of the MIT project.

The second major employer micro file is administered at the State level by the State Employment Security Agencies, and at the national level by BLS. The State agencies maintain micro files of all employers covered by unemployment insurance (UI) laws. (The California UI micro file was the basis for the Teitz study.) For the first calendar quarter of the year, each State Employment Security Agency submits to BLS a tape containing the name, account number, address, SIC code, 3 months of employment data, and total quarterly wages of each UI-covered establishment. This information serves as the sampling frame for most of the major BLS surveys. The UI universe file, in contrast to the D&B file, represents an almost complete census of nonagricultural firms and is updated on an annual basis.[7]

As previously indicated, the analytical use of the D&B file currently is limited by its noncomprehensive nature, a weakness in accounting for new births, the quality of the SIC coding, and the irregular updates of employer information. The D&B file has also been subject to irregular changes in file maintenance procedures which makes the development of a longitudinal data base even more difficult. These problems are, for the most part, handled better by the UI universe file. The major weaknesses of the UI file for micro analysis involve the difficulties in maintaining series continuity, determining employer affiliations, and identifying and breaking out the employment of multi-establishment firms.

A third major employer file, the Commerce Department's Standard Statistical Establishment List (SSEL), is currently being developed from various Census Bureau, Internal Revenue Service, and Social Security Administration records. The SSEL, when complete, will include all known multi- and single-establishment employers. Most data will be updated on an annual basis. The SSEL will be particularly strong in the breakout of multi-establishment employment.

Preliminary indications are that improvements in economic analysis could be achieved by coordinating the efforts of the MIT and Brookings project, and from the continued refinement and development of the UI and SSEL files. At the moment, however, most reconciliation work is hindered by the need to maintain confidentiality of employer responses to government surveys. Legislation is currently being developed by the U.S. Department of Labor to permit sharing of statistical information among data bases under procedures which would safeguard the confidentiality of responses, when this sharing is feasible. Each file could then serve, at a minimum, as a quality control check for the other files in terms of employer location, size, and industrial activity. Eventually, the attributes of these files might be combined to build an employer data base that would significantly improve the ability to trace the process of job creation. □

The future of work: does it belong to us or to the robots?

As the silicon chip helps chip away many factory and office functions, prospects are bright for both robots and microprocessors, but investment and other constraints seem to assure no revolutionary loss of employment

Sar A. Levitan and Clifford M. Johnson

Today, futurists are discussing the onset of a sweeping technological revolution, one which would rival or surpass the Industrial Revolution of the 19th century in importance. This envisioned social order has been given many names—"postindustrial," "technetronic," or "information" society. At the center of this flurry of interest in technological change is the microprocessor. While computerized automation has been theoretically feasible for more than a decade, large and expensive computer systems could produce cost savings only in the most massive industrial settings, and automated machinery could not be easily adapted to serve various production functions. Now, with the development of the microprocessor, these obstacles have been overcome and the potential uses of computerized machinery at the workplace have dramatically increased.

Microprocessor technology is best symbolized by the silicon chip, a miniaturized system of integrated circuits which can direct electrical current and, thereby, generate vast computational power. A silicon chip the size of one square centimeter can perform millions of multiplications per second, and has the capacity to store the texts of the Declaration of Independence, the Constitution, and a few chapters of the Federalist Papers. Technological advances are expected to result in at least a fourfold expansion of these capabilities within a decade, so that the microprocessors of the future will be extremely powerful computers on a single silicon chip or combination of chips. The reduction in size is astounding—today's hand-held programmable calculators have more computational power than the first full-scale computers built during World War II, computers which could have been "hand held" only by juggling 18,000 different vacuum tubes.

This miniaturization of computer technology is particularly important because it has been accompanied by dramatic cost reductions, making microprocessors economically competitive in a wide range of industrial applications. Once designed, silicon chips can be mass produced at a very low cost, and even further price declines are anticipated as volumes rise. As a result, a calculation which cost 80 cents to perform in the early 1950's costs less than one cent today, after adjusting for inflation. The combined reductions in size and cost of microprocessor technology have triggered renewed interest in prospects for automation and in the broader possibility of a wholesale transformation of modern society driven by these new technological capabilities.

The silicon chip is particularly important to economical automation because it provides the basis for fully integrating computer and machine. In industrial set-

Johnson is a research associate at the center. This article is adapted from their forthcoming book, *Second Thoughts on Work* (Kalamazoo, Mich., W.E. Upjohn Institute, 1982).

tings, the microprocessor makes possible the development of manufacturing machinery with unique adaptability. The great majority—at least 75 percent—of all manufactured goods fall into the category of shorter, lower-volume production runs, with only the most basic industries continuing to fit the mass-production stereotype. Technological advances in microelectronics, therefore, were an essential precondition to widespread automation, and the expanding use of reprogrammable machinery has triggered today's intense debate regarding the future of industrialized societies.

The potential impact of microprocessors is heightened by their seemingly endless number of applications. This new technology promises to alter not only the factory, but the office as well. Sophisticated word processors and computerized information storage and retrieval systems are becoming increasingly cost-effective, and because this new technology does not require knowledge of specialized computer languages, their growing use may raise traditionally low productivity among office workers. These office innovations are considered qualitatively different from previous office equipment which "mechanized" or "automated" routine tasks. While memory typewriters made an office worker's tasks easier, emerging computer technologies may change the means by which information is transcribed and made available to others. Again, only with the silicon chip has this decentralized use of computer technology at an affordable cost become possible.

'Robot revolution' coming

The use of the microprocessor to automate production functions is epitomized by the development of the robot. Prior to the last decade, robots were confined to the domain of children's stories and science fiction—their practical and efficient application in work settings was virtually inconceivable given the state of computer technology. The silicon chip has thrust robots from fantasy to reality, and the technology is being pursued with remarkable speed and vigor. A number of top computer companies are now considering entry into the robot market, and several large U.S. corporations have made commitments to purchase robots which are already available. The use of robots in manufacturing has nearly quadrupled between 1979 and 1981, and most analysts expect the sales curve to shoot higher during the next few years.[1] Most importantly, microprocessors seem to be in a prime position for the implementation of "learning curve pricing" strategies in which firms lower prices in anticipation of rising volumes and declining unit costs. The entry of large computer companies into the robot market could ensure this aggressive marketing stance and trigger a sharp rise in robot sales by 1990.

Today's robots bear little resemblance to the creations of screenplay writers and science fiction authors. Rather than some form of mechanical humanoid, industrial robots are characterized by mechanical arms linked to reprogrammable computers. An exact definition of a robot, as distinct from other automated machinery, eludes even industry representatives. The Robot Institute of America, an industrial trade group, stresses that it is the "reprogrammable and multifunctional" character of robots which is unique, allowing them to perform a variety of tasks.[2] And the emerging versions of robots are varied—the more extravagant include a "bureaucratic robot" which stamps signatures on letters, a robot "nurse" to assist handicapped persons in wheelchairs, a robot "janitor and guard dog" for the home, and "talking robots" which would advertise products or give job training to illiterates. Microprocessors are revolutionizing design methods for the development of new manufactured goods, and have become an integral part of nearly all modern research equipment so as to expedite lengthy data analysis.[3] Innovations such as voice-sensitive computers which can directly transcribe dictation into written text may be marketable within just a few years. It is this diversity of applications for microprocessor technology which distinguishes it from less significant innovations, and which has led futurists to predict a societal transformation "comparable with the agricultural revolution that began abouf 10,000 years ago, and with the industrial revolution."[4]

How far . . .

There is little consensus as to where the "robot revolution" is heading and how far it will go. The technology itself may be refined to such an extent that most factory work could be carried out by robots and automated machinery. For example, a study conducted at Carnegie-Mellon University asserts that the current generation of robots has the technical capability to perform nearly 7 million existing factory jobs—one-third of all manufacturing employment—and that sometime after 1990, it will become technically possible to replace all manufacturing operatives in the automotive, electrical-equipment, machinery, and fabricated-metals industries.[5] Yet these theoretical estimates of the potential for automation, which reach as high as 65 to 75 percent of the factory work force, do not reflect the rate at which the new technology will actually be introduced to the workplace. The pace of innovation will depend on the relative costs of labor and computerized technologies, as well as on broader levels of supply and demand for goods and services. Predictions of this nature are infinitely more difficult than abstract assessments of future technological capabilities.

The automobile industry offers an interesting case study, because it is probably the first manufacturing industry to aggressively pursue the use of robots in automated processes. The push toward automation in the auto industry is a response to both rising labor costs and growing concerns for quality control and competitiveness in international markets. Auto manufacturers already find it possible to operate robots for $6 per hour, well below the $20 per hour required for the pay and benefits of a skilled worker in 1981.[6] General Motors, aware of the growing use of robots by Japanese auto makers, predicts that by 1987, 90 percent of all its new capital investments will be in computer-controlled machines.[7] A 1980 survey conducted by the American Society of Manufacturing Engineers predicted that robots will replace 20 percent of existing jobs in the auto industry by 1985, and that 50 percent of automobile assembly will be done by automated machines (including robots) by 1995.[8] Even the United Auto Workers anticipates a 20-percent decline in membership by 1990 and has successfully obtained advance notice and retraining rights from auto manufacturers in a growing effort to gain protection from sweeping automation. Yet, few of these estimates include any consideration of the extent to which capital shortages confronting robot manufacturers and purchasers may limit the speed with which the new technology is adopted.

Projections of the impact of microprocessors on office employment are even more problematic, with analysts more frequently predicting the number of office jobs "affected" rather than eliminated by automation. The Carnegie-Mellon study argued that 38 million of 50 million existing white-collar jobs would eventually be affected by automation, while a vice president for strategic planning for Xerox Corp. offered the more conservative guess of 20 to 30 million jobs affected by 1990.[9] There is general agreement that office technologies will be changing rapidly, but little indication of whether the result will be reduced office employment, shifts in future employment growth, or simply higher levels of productivity in white-collar settings.

A 1982 study prepared for the International Labour Office found that microelectronic technology has not caused widespread displacement of office workers, but perhaps only because of the impact of poor economic conditions on the rate of diffusion of the new technology in office settings. Selected case studies of the banking and insurance industries suggested that new job opportunities were being created, but the skills made redundant by new technologies were generally inappropriate for those emerging opportunities. The report stressed that this trend poses special threats to employment prospects for women, and called for additional education and training efforts to close the "skill gap" caused by the use of microprocessors in office jobs.[10]

Perhaps the greatest fears that automation will lead to widespread unemployment have been voiced, not in the United States, but in Western Europe. For example, two British authors have predicted nothing short of the collapse of work as a social institution in an era of microprocessors:[11]

> It is impossible to overdramatize the forthcoming crisis as it potentially strikes a blow at the very core of industrialized societies—the work ethic. We have based our social structures on this ethic and now it would appear that it is to become redundant along with millions of other people.

In West Germany, studies of the impact of automation on future employment levels commissioned by the Bonn government projected that the number of jobs in 1990 will at best be marginally above 1977 levels—a pessimistic view in light of anticipated population growth. The issue of technologically induced unemployment increasingly is capturing the attention of West European leaders, and unions in Italy, Germany, and elsewhere are responding with demands for shorter workweeks to protect employment levels. Perennial fears that machines would replace workers have never been fulfilled, but European futurists insist that it will be different this time.

. . . and how fast?

While the impact of automation in the past has been offset by the emergence of new industries and by growth in the service sector of the economy, these avenues for employment growth may indeed be less open in an era of microprocessors. The electronics industry, which supports this computerized technology, certainly will experience rapid growth in the coming decade, but a 1979 survey of the world electronics industry prepared for the Organization for Economic Cooperation and Development revealed that the internal use of its own technology will keep employment growth in this sector to a minimum.[12] It is this "reproductive" potential of computerized technology—the prospect of robots building robots—which challenges traditional patterns of employment growth through new industries. And to the extent that the microprocessor will affect service as well as manufacturing industries, even the recent trend of expanding service employment may fail to provide jobs.

In spite of these relatively unique characteristics of microprocessor applications, predictions of immediate and massive job losses tend to ignore the market forces which slow the pace of technological change. As stressed in recent research by the Bureau of Labor Statistics, many factors limit the speed of diffusion of technological change and thereby mitigate possible employment implications. The size of required investment, the rate of capacity utilization and the institutional arrangements within industries all can act as "economic governors" which slow the adoption of automated technologies.[13]

Virtually all capital-intensive industries have a massive investment in existing plant facilities, and they cannot afford to squander these resources through the wholesale replacement of working machinery. More importantly, the financial constraints on capital formation necessarily limit the rate at which new technologies are introduced. In this context, Joseph Engleberger, president of Unimation, Inc. (the Nation's largest robot manufacturer), has dismissed predictions of galloping automation, noting that even the replacement of 5 percent of all blue-collar workers in Western industrialized nations would require investments totaling $3 billion in each of the next 40 years.[14] While microprocessor technology may be promising in its flexibility and potential efficiency, industries must be able to afford the new acquisitions in order to use them.

A less tangible but perhaps equally important force limiting the expansion of computer technology lies in the attitudes of both workers and consumers. While a computer may be able to diagnose medical problems, its bedside manner may be less than comforting. Similarly, word processors and telephone answering systems may alter clerical roles, but most executives will not want to forgo the convenience offered by their personal secretaries. People can hear the best music in the comfort of their homes, but flock to concert halls to hear lesser performances. Even on the assembly line, where robots may be perfectly suited for production processes, the aversion of managers and workers to such unfamiliar companions may hamper their smooth and rapid assimilation at the workplace. These psychological barriers cannot be factored into equations of economic efficiency, but they are likely to slow the pace of technological change nonetheless.

Will workers become obsolete?

The picture which emerges when the functioning of capital markets and work organizations are considered is one of evolutionary rather than revolutionary change. With annual sales of robots well below 10,000 in a labor force of more than 100 million, it will be some time before computerized technologies make a major dent in aggregate employment levels. This perspective is emphasized by Robotics International, a professional group which polled 100 users and manufacturers of robots. Based on the responses, the group concluded that robots are likely to replace 440,000 rather than a million workers by 1990, and that all but 5 percent of the displaced workers would be retrained rather than dismissed.[15] The relative lack of union concern in the United States over aggregate job losses through automation also stems from this belief that the pace of innovation has been exaggerated. William Winpisinger, president of the International Association of Machinists, has argued that the replacement of human skills with computerized machinery will occur slowly and that a shortage of skilled workers will remain our most pressing manpower problem.[16] No doubt, unions will continue to seek guarantees of job security in some industries, and collective bargaining may gradually extend to include management investment decisions.

In the more distant future, no one can be sure where new employment growth will occur. Expectations of a workless society still linger; as described in one forecast:[17]

> Earning a living may no longer be a necessity but a privilege; services may have to be protected from automation, and given certain social status; leisure time activities may have to be invented in order to give new meaning to a mode of life that may have become economically useless for a majority of the populace.

The literature in recent decades has been replete with speculations on how people would cope with the loss of meaningful work roles, or how society would allocate and distribute wealth in the absence of strong ties between work and income.[18] Even for those who reject such forebodings, the belief in continued employment growth admittedly contains as much faith as foresight.

Still, there seems little likelihood that the worker will become obsolete in the foreseeable future. In one sense, past waves of automation have created dislocations, but it has been distributed throughout the labor force in the form of benefits and social progress—shorter workweeks, more vacation time, longer training and education, earlier retirement, child labor laws, and welfare and unemployment payments. We can expect this trend to continue, particularly as labor seeks assurances of job security. Assuming a healthy rate of economic growth during a period of innovation and increasing automation, it is also likely that levels of aggregate demand will support the emergence of new goods and services. Rising expectations alone will cause Americans to translate productivity gains into higher standards of living instead of less work, a pattern which has held for centuries. The period of adjustment which lies ahead may not be painless, but it seems that work is here to stay. ☐

Smoothing the transition

Union resistance to labor-saving technical change within an industry can often be moderated by careful management of change, which will minimize its effect in creating unemployment. This is much more difficult in the case of interindustry effects, since an enterprise in one industry is unlikely to be concerned with the effects of its decisions on employment in another industry. Technical change often produces losses for investors who have invested in equipment and skills that are made obsolete. Where the investment is embodied in people rather than in machines, the human problems it causes are more severe and less tractable. Those outside the union movement cannot condone a position that blocks technical progress, but they can approve one that uses some of the fruits of progress to give reasonable compensation to workers for the loss of their livelihood.

Helping labor and management see and solve problems

A mediator can help improve an unhealthy labor-management relationship by recognizing the symptoms, making an accurate diagnosis, and carefully prescribing appropriate remedies

JOHN R. STEPP, ROBERT P. BAKER,
AND JEROME T. BARRETT

The Federal Mediation and Conciliation Service has recognized that the effective promotion of labor-management peace requires more than just an "eleventh-hour" appearance at the bargaining table by its mediators. Like most other professional organizations that respond to human emergencies, the service has learned that by blending prevention with treatment its resources are used more efficiently.

The preventive mediation function requires the mediator to be alert to symptoms of untoward labor-management relationships, to diagnose the problems accurately, and to prescribe effective remedies.[1] The nature and severity of the symptoms must be recognized and traced to their source; the remedy must be suited to the location of the symptoms in the labor or management hierarchy, or both; and the parties must be persuaded that the cure is preferable to the disease and is clearly in their own self-interests.

This article extracts from accumulated experience those principles on which a prescriptive model for improving labor-management relationships can be built.[2] This empirical model is erected on the perceptions and experiences of the authors, all of whom are or have been Federal mediators.[3]

Recognizing the symptoms

Mediators are uniquely positioned to detect the danger signals emanating from a poor labor-mangement relationship. When involved at the collective bargaining table in dispute mediation, the mediator can make a reasoned judgment as to the nature of the relationship behind the conflict. This is done by examining the issues, assessing each side's internal relationships, and testing and verifying these impressions through indepth private discussions with both parties.

Numerous issues, especially noneconomic or language items, are often symptomatic of underlying problems which are being addressed in a circuitous manner. When this is the case, a contractual agreement may be no more than a bandage on a festering wound. The underlying problems have neither been identified nor addressed and certainly have not been resolved.

Every mediator, at one time or another, has entered a negotiation shortly before a strike deadline, only to be confronted with many unresolved issues. In private discussions with the moving party, usually the union committee, the mediator learns that these issues are an attempt to send the other party "a message." The message is that there is enormous dissatisfaction with "busi-

---

John R. Stepp is Director, Office of Labor-Management Relations Services, U.S. Department of Labor; Robert P. Baker is District Director, Western Region, San Francisco, Federal Mediation and Conciliation Service; and Jerome T. Barrett is Director and Associate Professor of Industrial and Labor Relations, Northern Kentucky University, Highland Heights.

ness as usual" on the shop floor and that problems are not getting resolved. Resentment is bubbling over onto the bargaining table in the form of contract issues. The bargaining table is an ill-equipped forum for the effective resolution of these underlying problems. During crisis negotiations it is very difficult to negotiate an improvement in attitudes or a better labor-management relationship.

Faced with a rapidly approaching deadline, the best the mediator can hope for is that some issues can be resolved through catharsis and others quietly dropped because they are not strike-related. If a tentative agreement is reached, the mediator's relief may be brief because the membership's frustrations may surface again in their refusing to ratify the agreement. Even with ratification, there remains a strong suspicion that all is not well and that the administration of this contract and the negotiation of the next are likely to be fraught with difficulty. This perception is often shared by negotiators, too.

The mediator may also become aware of a deteriorating labor-management relationship through ways other than his or her personal involvement in contract negotiations. Through such professional and community organizations as the Industrial Relations Research Association, the mediator can learn of problems. Also, in monitoring dispute cases, he or she has daily contact with representatives of labor and management; through casual conversation, there is much opportunity to learn of labor relations problems in a particular plant or location.

Similarly, relationships plagued by frequent, long, or bitter strikes; wildcat strikes; high grievance levels; numerous arbitrations; or other obvious signs such as job losses in a declining business enterprise, are symptoms which will catch the mediator's attention. Once alerted, he or she can seek confirmation from the labor and management representatives at the site.

Another means of mediator awareness is through communiqués from the affected parties. Because the Federal Mediation and Conciliation Service is annually involved in more than 1,000 technical assistance endeavors, the awareness of the availability of this service among labor-management practitioners assures numerous requests. When contacted, the mediator will begin exploratory meetings with the parties to determine the nature, location in the organization, and extent of the problems.

Diagnosing the problem

Having detected danger signals, the mediator must guide both parties through a joint analysis of the problems in order to determine their seriousness and exact location. Until this diagnosis is completed, no remedy can be prescribed. The character of a labor-management relationship may be viewed along a simple continuum consisting of three benchmarks: *conflict*, *detente*, and *accommodation*.[4]

An employer at the *conflict* end of the continuum never really accepts the union: " . . . he does not yield to the union even a narrow, restricted scope until he literally has to; and he looks for the first opportunity to get rid of the intruder. His acceptance of joint dealings is an 'imposed acceptance,' imposed by law and by union power."[5]

Under *detente*, the midpoint of the continuum, each side accepts the other's institutional legitimacy but exercises its relative strength to obtain the best deal. Each adopts a "win some, lose some" approach. They fight, but the conflict is held within accepted limits; there is a conscious effort to avoid pain and serious injury to one another. Parties at the *accommodation* end of this scale strive to reduce the level of contention. When differences do occur, they are processed with minimum emotion through agreed-upon procedures with equity being a realistic and desired goal for both. "They have proved themselves willing to compromise whenever possible, to conciliate whenever necessary, and to tolerate at all times."[6]

The three benchmarks can be used by the mediator to determine the severity and types of problems the parties have. Relationships characterized by *conflict* will have the most serious problems, reflecting distrust, hostility, and suspicion; those characterized by *accommodation* will have the least severe problems, arising from human failures in communications, consistency, and concern for the points of view of others.

The next segment of the model directs the mediator's diagnosis to a determination of the location of the problem within the respective organization. One inhibitor to accurate diagnosis is the diffusion of authority in complex, multilayered, and interdependent labor-management organizational structures. A systematic examination of the various intraorganizational dimensions and their interrelationships is needed to locate and address the source of the problem. Because the structures of most labor organizations are reactive to and thus closely parallel the management structure to which they relate, more attention will be given to the structure of management in labor relations matters.

Management can generally be regarded as conducting labor relations on three levels. (On occasion these levels may be extended or compressed.) The top level is one of decisionmaking, usually personified by either a vice president of labor relations or a labor relations director. This level formulates, delivers, and implements corporate policy on its own initiative or as an operating arm of higher-level management policymakers. The union counterpart of this level is usually an international representative.

The mid-level can be characterized as one of implementation for labor relations decisions and policies. Within management, this level would generally be staffed by either a plant manager or a department head who formulates very little policy but has, instead, the important responsibility of supervising and coordinating the implementation of policies established at the top level. Business agent or local president are usually the titles of union officials at this level.

The lowest management level is populated by first-line supervisors. They face the difficult task of confronting the real world armed only with the policies supplied and precedents established. Here are discovered both the flaws and strengths of overall policy. The union counterpart at this level is the steward.

A thorough examination of the parties' relationship requires a look at the relationships between levels within each structure, as well as across the table, which symbolizes the classic area of contention. Given three existing levels of labor-management interaction within a bargaining unit, each level having 1 of 3 possible characters, a diagnosis may theoretically yield 27 possibilities.[7]

In this article, we will not attempt to deal with 27 different variations, several of which have only a theoretical existence and are not plausible outcomes. For example, this would be true when accommodation existed at the supervisor/steward level, but at all higher levels the parties were locked in conflict. Accommodation could not realistically exist between foreman and steward, except momentarily, if conflict were the prevalent mode between plant manager and business agent. Two corporals in opposing armies cannot wage peace while their generals are waging war, lest they risk dismissal for treasonous behavior.[8] More importantly, to examine all 27 possibilities would emphasize detail over the more generic and fundamental concepts.

Prescribing a remedy

Having diagnosed the relationship and the possible location of the problem, the model's remaining segment concerns the prescribing of remedies. Labor-management relations improvement remedies are few—there are presently three primary items: Relationships by Objectives programs, labor-management committees, and joint training programs. Variations exist of each, especially the latter two.

Relationship by objectives. In the Relationships by Objectives program, mediators provide the expertise for guiding labor and management toward basic changes in their relationship.[9] Both are brought together by mediators to analyze their problems, to decide what their common objectives should be, and to reach agreement on goal implementation. Since the program was introduced by the Federal Mediation and Conciliation Service (FMCS) in 1975, 100 Relationships by Objectives projects have been completed in some of the most difficult labor relations situations in American industry.

Currently, the program is being used almost exclusively in situations following protracted strikes or where there are volatile labor-management histories. The criteria established by the FMCS as a prerequisite for conducting such programs are that both parties must be sufficiently concerned about their divisive relationship and committed at all levels to do something about it. In return, the FMCS commits itself to assist the parties in rebuilding their relationship and thus to reduce the prospects of strikes in subsequent negotiations. (A Relationships by Objectives program may result in the parties identifying a need for a labor-management committee or for training.)

Labor-management committees. In recent years, more than 300 labor-management committees have been formed annually by employers and unions with the assistance of FMCS mediators. The structure and goals of labor-management committees vary greatly, but most share the essential need for representatives of labor and management to join together and talk about mutual problems. These committees complement the traditional collective bargaining relationship. They are an implicit recognition that the parties have much in common and that their relationship need not be totally adversarial. Through effective committees, joint problem-solving can take place which strengthens mutual credibility and tends to improve relationships.

Joint training programs. Successful labor-management relations are less a function of the quality of negotiations than of the day-to-day implementation and administration of the labor agreement. The majority of this work is done by the first-line supervisor and the union steward. If their performance is below standard, relations suffer. Consequently, most of FMCS' preventive activities have been directed toward this group.

Supervisor-steward training does have considerable value in the development of a work atmosphere which is conducive to labor peace and the quick and effective resolution of labor-related problems. Training sessions, which use a variety of instructional techniques and focus on subjects such as communications, leadership, and grievance handling, are a vehicle whereby adversaries can set aside their stereotyped images and view one another in a nonthreatening light, thus seeing, perhaps for the first time, their commonalities. The FMCS conducts 400 to 500 such joint training programs annually.

These training programs are tailored to the perceived needs of the supervisor-steward audience, and are structured to encourage class participation. Using a combination of lecture, audio-visual materials, and workbooks for the participants, the mediator leads discussions into such areas as:

- understanding the supervisor-steward relationship;
- making the supervisor-steward relationship work;
- providing effective leadership; and
- handling problem situations.

These programs are not intended to provide instant solutions to complex problems. They are designed to enable the participant, working with others in the group and under the guidance of a mediator, to come up with his/her own insights which, it is hoped, will be wisely applied over time to improve their relations.

Setting priorities

In selecting a remedy, order is important. One must focus first at the highest level in need of attention. Higher-order problems must be resolved or neutralized before those of a lower level are addressed.

If the labor-management problems are severe, and are located in the top or middle levels of the respective organizations, then the Relationships by Objective program should be considered as a possible remedy. Through the program, the parties have an opportunity to recast their relationship or to start anew, provided there is mutual acknowledgment of serious problems impairing the relationship, and genuine commitment to change.

Once the program has been successfully applied, *detente*, and rarely, *accommodation*, would be expected in lieu of *conflict*. Assuming the most likely, *detente*, the parties are now in a position to build together a better relationship. To assure further positive momentum and continued improvement, a labor-management committee is usually needed.

If nurtured and sustained, labor-management committees have demonstrated their capability for improving labor relations. The most visible level of improvement is likely to be between the top plant management and the business agent or local union president. If the committee is really working, it will also affect the plant floor. Consequently, through effective applications of such committees, all mid-level outcomes have the potential of being elevated to the *accommodation* mode.

In many cases involving labor-management committees, a problem that is often identified as an impediment to a good relationship is the inability of stewards or supervisors, or both, to dispose of grievances successfully. This can generally be attributed to some combination of three factors: (1) an unwillingness to reach an agreement—a preference for sustaining the conflict, (2) the absence of perceived authority to settle the problem, or (3) the lack of knowledge or technical ability to handle grievances. Each of these causes can be successfully tackled by the labor-management committee. The firs two can be addressed through separate consultation within each party, so that agents at the lower level realize their superiors are expecting most problems to be resolved at that level.

If the remaining problem is simply a technical inability to meet labor relations responsibilities, the most effective antidote is training. Through joint training o supervisors and stewards, the groundwork may be laid for a better relationship. Effective joint training usually emphasizes the building of problem-solving and interpersonal skills, and better understanding of respective roles and the benefits of working together.

Equipped with an improved understanding of their roles and the prerequisite skills for doing their jobs, and encouraged by support from the top and middle levels, discord and discontentment at the lower level can be converted to *accommodation*.

Third party audits

The model that we have evolved consists of: three organizational levels within labor and management; three characterizations of the relationship which determine the type and severity of the problem; and three remedial approaches. However, it has not been suggested in any detail how to analyze a labor-management problem when applying the model; rather we have spoken of the mediator recognizing danger signals and observing issues and relationships, all of which implies an intuitive, ill-defined, and artistic process. This method usually provides a sufficiently accurate diagnosis in cases in which the mediator knows the parties well, or the problems are relatively obvious, or both; but in other situations a more rigorous approach is needed to apply the model. For this purpose, we will describe a diagnostic process used in organizational development and human resources development (training needs assessment).[10] Discussion will center on joint training at the supervisor/steward level, but with minor modifications, the process could be used at other levels or when other remedies are proposed.

The diagnostic procedure, developed by Geary Rummler, focuses on a "human performance" audit.[11] For him, human performance is composed of: (1) the job situation or occasion to perform; (2) the performer; (3) the behavior (action or decisions) that is to occur; and (4) the consequences of that behavior to the performer.[12] The advantage of using a performance audit is that it forces the specific source of the undesirable behavior to be identified.

A second feature of Rummler's audit is the determination of the economic consequence of poor performance. In other words, having determined by the audit model that undesirable performance is a result of a lack of feedback to a supervisor about his or her work, for example, the question is asked: does it *really* make any difference or enough difference to require change? The result of this questioning will be to consider first those performance problems which are most economically important to the organization.

A very sophisticated or extremely simple audit can be used, depending upon the amount of time available, the complexity of the organization, and the functions being audited. This audit of performance can be used on all three levels of labor relations concurrently, but we will apply it only to the lower level.

The basic components of the Rummler approach can be retained in a streamlined audit by using this series of questions to identify sources of the problems and to analyze them:

I. General lead-in questions
   1. How do you know you have a problem?
   2. How will you know when the problem is solved?
   3. How long has this been a problem?
   4. How general is the problem?

II. Questions on the job
   1. What is the desired performance?
   2. What are the job standards?
   3. Who says that these are the standards?
   4. Does everybody agree on these standards?

III. Questions on the performer
   1. What are the specific differences between actual and expected performance?
   2. Has anyone ever performed as expected?
   3. Who?
   4. When?
   5. How many individuals are now performing below standard?

IV. Questions on behavior
   1. Did the steward or first-line supervisor ever perform properly?
   2. Could they perform properly if their lives depended upon it?
   3. If they could perform properly, would they?

V. Questions on the consequences of performance
   1. Does the steward or first-line supervisor whose performance is below standard know:
      a. What is expected of him or her?
      b. What he or she is not performing correctly and exactly how far he or she is from expected performance?
      c. How to perform correctly?
      d. When to perform?

VI. Questions on feedback
   1. What positive or negative consequences, or both, of performing correctly or incorrectly can the first-line supervisor or steward expect from:
      a. Higher ranking officials within the company or organization?
      b. Subordinates?
      c. Associates at the same level?

VII. Questions on economic costs and priorities
   1. What does it cost the employer or union not to remedy the performance problem?
   2. What is the priority on remedying any performance problem?

A few examples will illustrate how these questions produce relevant information on performance and economic priorities:

- Under II, questions 1, 2, and 3 could lead one to discover that the union policy is unclear on whether a steward is expected to anticipate and solve problems before they become formal grievances.
- Under III, question 5 could disclose that first-line supervisors in only 2 departments in 20 have performance problems.
- Under IV, questions 2 and 3 could reveal that motivation and interest are the source of the performance problem, not knowledge or skill.
- Under V, question 1 could divulge that the first-line supervisor is aware of only one-third of the tasks expected of him or her.
- Under VI, question 1 might reveal that the steward gets no positive feedback on his or her performance.
- Under VII, question 1 might show that the failure to properly investigate a grievance, prior to committing it to writing, doubled the length of time required to process it through the first two steps of the grievance procedure.

When the audit is completed, the mediator will have a complete list of the performance problems in the area under study, which will include an identification of the sources of the problems, and economic priorities based on the cost of the problem to the organization.

Following an analysis of this list, the mediator could act as an adviser to labor and management in determining the appropriate remedy. Some problems are more susceptible to a training solution, others to a labor-management committee or a Relationships by Objectives program, and some will require structural and policy changes. In each instance, the mediator will work with the parties to resolve the performance problem and improve their relationship.

Conclusions

Before any labor-management relationship can be improved, the parties to that relationship must both be dissatisfied with the status quo and have before them some blueprint which, if followed, has a reasonable chance of succeeding.[13] [14] In many cases, labor-management relationships are operating at a suboptimal level. This can happen for many reasons; for example, one or both sides prefer it that way, they are not prepared to incur the political or economic costs they attach to improvement, they do not know how to gain the necessary credibility to move jointly forward, or they simply do not know what to do.

Often a trusted third party can diplomatically allow the parties to focus on shortcomings in a relationship, by minimizing political and economic costs of change, promoting trust and cooperation, and assisting both sides in developing a roadmap which, if followed, should lead to a positive, constructive relationship. □

FOOTNOTES

[1] Section 203 (A) of the Taft-Hartley Act states: "It shall be the duty of the Service, in order to prevent or minimize interruptions, of the free flow of commerce growing out of labor disputes, to assist parties to labor disputes in industries affecting commerce to settle such disputes through conciliation and mediation."

During the discussion on the floor of the Senate of Bill S.1126 (subsequently compromised to become the Taft-Hartley Law), Senator Irving Ives of New York made the statement: "A great lack at the present moment in the field of mediation is measures by which we may prevent industrial strife as well as cure it after it has begun. That, of course, is contemplated under the new title." (*Congressional Report*, p. 4,590, 5–6–47.)

[2] It is interesting to note that the Federal Mediation and Conciliation Service Preventive Mediation function started during the same period (late 1940's) as the early applications of contemporary behavioral science to organization and management. But there is little evidence that the service benefited in any systematic way from developments within behavioral science until the 1970's. The introduction of the Relationships by Objectives program in 1975 (see discussion on p. 17 of this article) was influenced by the work of Blake and Mouton, particularly Robert R. Blake, Herbert A. Shepard, and Jane S. Mouton, *Managing Intergroup Conflict in Industry* (Houston, Gulf Publishing Co., 1964), p. 210; and Robert R. Blake, Jane S. Mouton, and Richard L. Sloma, "The Union-Management Intergroup Laboratory: Strategy for Resolving Intergroup Conflict," in Warner Burk and Harvey A. Hornatein, eds., *The Social Technology of Organization Development* (Fairfax, Va., NTL Learning Resources Corporation, 1972), pp. 101–26.

This lack of behavioral science influence on preventive mediation during these 30 years is understandable because Federal Mediation and Conciliation Service mediators are pragmatic individuals caught up in practicing their art; they are not inclined to seek help or guidance from theorists and academics. Moreover, even the behavioral scientist makes limited claims for the application of his work to the practitioner. See George Strauss and others, eds., *Organizational Behavior: Research and Issues* (Madison, Wis., Industrial Relations Research Association Series, 1974), p. 2, which quotes with approval Harold L. Wilensky, writing on the same subject in 1957: "Not everything done by the social scientist can or should help the practitioner . . . . the social scientist's job is basically different from the executive's job . . . . much of what he comes up with is of limited use to the practitioner."

Writing 5 years later on the question, "Can Social Psychology Contribute to Industrial Relations?" Strauss said, "From 1960 on, psychological contributions to industrial relations were almost nonexistent . . . " See Geoffrey M. Stephenson and Christopher J. Brotherton, eds., *Industrial Relations: A Social Psychological Approach* (Chicheston, England, John Wiley & Sons, 1979), p. 371.

[3] The views expressed do not necessarily reflect those of the Federal Mediation and Conciliaton Service.

[4] A similar continuum of labor-management relations consisting of armed truce, working harmony, and union-management cooperation was proposed in Frederick H. Harbison and John R. Coleman, *Goals and Strategy in Collective Bargaining* (New York, Harper & Brothers, Publishers, 1951), p. 19.

Another more complex model for analyzing labor-management relations is described in Leon Meggison and C. Ray Gullett, "A Predictive Model of Union-Management Conflict," *Personnel Journal*, June 1970, pp. 495–503.

[5] See Benjamin M. Selekman, Sylvia K. Selekman, and Stephen H. Fuller, *Problems in Labor Relations* (New York, McGraw-Hill Book Co., 1950), p. 7.

[6] "Problems," p. 8.

[7] $D = L^G$ where D is the number of diagnostic outcomes, L is the number of levels in the organization (3), and G is the number of possible characterizations of the relationship between the parties (3). Hence, $D = 3^3$ or 27.

[8] However, it should be noted that a very bad relationship (conflict) may exist at a lower level even though there is a very good one at the next higher level (accommodation). Two generals can be pursuing peace while the battle rages.

[9] For more background on Relationships by Objectives program, see John J. Popular, "Labor-Management Relations: U.S. Mediators Try to Build Common Objectives," *World of Work Report I*, September 1976, pp. 1–3; Thomas A. Kochan, *Collective Bargaining and Industrial Relations* (Homewood, Ill., Richard D. Irwin, Inc., 1980); and Anthony V. Sinicropi, David A. Gray, and Paula Ann Hughes, *Evaluation of the Federal Mediation and Conciliation Service's Technical Assistance Program in Labor-Management Relationships by Objectives (RBO)*, unpublished, Federal Mediation and Conciliation Service, 1978.

[10] In the field or in organizational developments there are a number of diagnostic processes for searching out and assessing organizational problems. See for example: Robert R. Blake and Jane S. Mouton, *Corporate Excellence Diagnosis: The Phase 6 Instrument* (Austin, Tex., Scientific Methods, 1968); J. Richard Hackman and Greg R. Oldhan, "Development of the Job Diagnosis Survey," *Journal of Applied Psychology*, 1975, vol. 60, pp. 159–70; Ralph H. Kilmann and Kenneth W. Thomas, "Four Perspectives on Conflict Management: An Attributional Framework for Organizing Descriptive and Normative Theory," *Academy of Management Review*, 1978; vol. 3, pp. 59–68; John P. Kotter, *Organization Dynamics: Diagnosis and Intervention* (Reading, Mass., Addison-Wesley, 1978); Paul R. Lawrence and Jay W. Lorsch, *Developing Organizations: Diagnosis and Action* (Reading, Mass., Addison-Wesley, 1969); Harry Levinson, *Organizational Diagnosis* (Cambridge, Mass., Harvard University Press, 1972); and Rensis Likert, *The Human Organization: Its Management and Value* (New York, McGraw-Hill Book Co., 1967).

[11] Geary A. Rummler, "The Performance Audit," in Robert L. Craig, ed., *Training and Development Handbook* (New York, McGraw-Hill Book Co., 1976, 2d ed.).

[12] Rummler, "The Performance Audit."

[13] Dissatisfaction with the status quo is found in organizational development efforts: "The fundamental reason some crisis or pressure seems to be so important in setting the stage for change is that it creates a state of readiness and motivation to change. Kurt Lewin called this the 'unfreezing stage' at which old beliefs, values, and behaviors lose strength in the face of data that disconfirm the manager's (unionist's) view of his (their) organization's effectiveness." Michael Beer, *Organization Change and Development: A Systems View* (Santa Monica, Calif., Goodyear Publishing Co., 1980), p. 48.

[14] The need for a plan in order to facilitate change is also found in the Organizational Development literature: "Successful change efforts require new models for looking at organizational problems and/or new ideas for structuring or managing the organization. New models may come in the form of a new organizational design, accounting system, planning systems, or personnel policy." (See Beer, "Organizational Change," p. 50.)

Millwork industry shows slow growth in productivity

During 1958–80, output per hour advanced at half the rate of growth for all manufacturing industries, reflecting unstable demand and low capital investment

JACK VEIGLE AND HORST BRAND

Labor productivity in the millwork industry rose at an average annual rate of 1.4 percent from 1958 to 1980,[1] a modest advance when compared with total manufacturing. Over this period, output in millwork increased at a rate of 2.7 percent annually and employee hours at 1.3 percent. The productivity rise partly reflected low growth in capital investment, particularly over the past decade, and evidently slow diffusion of modernized production technologies. These factors, combined with instability in demand for the industry's products, retarded productivity. Industry demand depends mostly upon residential construction, where fluctuations have been frequent and substantial.

The overall rate of increase in the productivity of the millwork industry reflects basically two periods in each of which the productivity movements differed significantly. Between 1958 and 1972, productivity rose at an average annual rate of 2.6 percent, rising 42 percent by 1972, to a high for the period (107.2 on a 1977=100 basis). However, from 1972 to 1980, productivity declined at a rate of 1.4 percent a year, or by 13 percent. By contrast, productivity in the private nonfarm business economy continued to advance, although at a slower rate than earlier. The following tabulation shows the pertinent comparisons (average annual rates, in percent):

	1958–80	*1958–72*	*1972–80*
Millwork industry	1.4	2.6	-1.4
Private nonfarm business	1.8	2.1	0.9
Manufacturing	2.8	3.1	1.8

Year-to-year changes in millwork productivity were quite volatile, ranging from a 12-percent rise (in 1967) to a 9-percent drop (in 1974). Productivity declined in 8 of the 22 years surveyed. In such years, output either fell more than employee hours or rose less. In 10 of the years of rising productivity, output gains exceeded employee hour increases. But in the other years of rising productivity, productivity improvements were associated with output declines being smaller than employee hour reductions.

Output and demand

The millwork industry manufactures wood window units, including sashes; window frames; doors and door frames; moldings; and stairs. In 1977, one-quarter of the industry's output consisted of window units and related items; and close to two-fifths of doors, including garage doors. Moldings represented another fifth of output. Approximately three-fourths of the industry's output was used in residential housing, including additions and alterations; small amounts of output were used in commercial and educational buildings, prefabricated wooden buildings, and in trailers and other transportation equipment. Millwork output is thus linked mainly to residential construction markets.

Output of millwork products rose at an average annual rate of 2.7 percent between 1958 and 1980, about in line with the trend in the deflated value of new residential housing units plus additions and alterations. Output movements during the period were characterized by differences in average annual rates of change between 1958–72 and 1972–80, which were similar to the variations in productivity movements noted above. During

---

Jack Veigle and Horst Brand are economists in the Division of Industry Productivity Studies, Bureau of Labor Statistics.

1958–72, output rose 3.6 percent annually, in 1972–80 it declined 0.9 percent a year. Millwork output fluctuated generally less on a year-to-year basis than residential building activity. The lesser amplitude of millwork output fluctuations may partially relate to inventorying practices of jobbers through whom much of industry sales are conducted.

Millwork output was strengthened, particularly during the 1960's, by increases in the square foot area of single-unit housing—indicating more rooms as well as larger room size, hence more doors, windows, and moldings. During the study period, square foot area per housing unit rose more than 20 percent.[2] While the number of 1 to 3 room housing units being added to the housing stock declined between the 1960's and 1970's, additions to 4- and 6-room units grew strongly; the increment in 5-room units remained roughly the same. Units with 7 rooms or more recorded particularly strong increases during the 1970's. However, multi-unit dwellings gained in relative importance during the early and mid-1970's, when apartment construction rose to 37 percent of all private housing starts, up from 33 percent in the 1960's. Because only a relatively small proportion of millwork output is used in such construction, the sharp increase in multi-unit starts probably offset somewhat the demand from single-unit residential starts. (For example, more than 80 percent of window units installed in apartment buildings are of aluminum, as against 50 percent for 1- and 2-unit residences.)[3]

There were other factors pertaining to housing which sustained millwork output during most of the period studied. For example, the number of homes built with two stories or more, 17 percent of total starts in 1964, rose to 28 percent in 1978, indicating a greater demand for stairs, moldings, and other millwork items. The proportion of homes built with 1- and 2-car garages grew from 63 percent in 1963 to 74 percent in the late 1970's—spurring the demand for garage doors, an estimated 85 percent of which are made of wood.[4]

The demand for window units has of course fluctuated with housing starts. On balance, it rose substantially during the 1960's, and fell off somewhat in the 1970's. Demand in the 1970's was also crimped by a decline in the number of windows per dwelling unit, partially associated perhaps with builders' efforts to make homes more energy efficient; and by competition from aluminum and steel windows. Currently, the millwork industry accounts for one-third of all residential window installations, aluminum and, to a small extent, steel, making up the other two-thirds. Except for 2 years in the mid-1970's, when aluminum window prices rose relative to wooden ones, the industry's share of the window market has steadily declined from roughly one-half of the total in the late 1950's.[5]

Growth in the industry's output of doors has also been slowed by competitive materials. The industry

Table 1. Productivity and related indexes for millwork industry, 1958–80
[1977 = 100]

Year	Output per hour			Output	Employee hours		
	All employees	Production workers	Nonproduction workers		All employees	Production workers	Nonproduction workers
1958	75.6	77.0	70.7	58.5	77.4	76.0	82.8
1959	71.7	72.4	69.7	61.2	85.3	84.5	87.8
1960	73.2	74.8	67.7	55.7	76.1	74.5	82.3
1961	76.9	78.1	72.6	56.6	73.6	72.5	78.0
1962	78.1	78.8	76.3	59.7	76.4	75.8	78.2
1963	86.0	86.0	86.5	68.1	79.2	79.2	78.7

1968	93.9	93.7	96.0	78.7	83.8	84.0	82.0
1969	96.3	96.6	95.7	80.4	83.5	83.2	84.0
1970	95.9	97.6	89.7	77.1	80.4	79.0	86.0
1971	95.9	95.3	99.3	84.0	87.6	88.1	84.6
1972	107.2	104.5	121.6	103.6	96.6	99.1	85.2
1973	102.3	101.6	106.7	104.7	102.3	103.1	98.1
1974	92.7	94.4	85.5	84.6	91.3	89.6	99.0
1975	100.2	102.6	90.9	84.1	83.9	82.0	92.5
1976	99.1	99.6	97.3	92.5	93.3	92.9	95.1
1977	100.0	100.0	100.0	100.0	100.0	100.0	100.0
1978	91.5	91.5	92.0	96.2	105.1	105.1	104.6
1979	93.9	95.2	88.2	96.2	102.5	101.1	109.2
1980	93.7	97.2	80.4	87.1	93.0	89.6	108.4
	Average annual rates of change (in percent)						
1958–80	1.4	1.4	1.3	2.7	1.3	1.3	1.4
1975–80	−1.7	−1.4	−2.8	0.7	2.4	2.2	3.6

accounted for close to three-fifths (by value) of all doors installed in new residential dwelling units in 1977, a slight decrease from earlier years.

Inroads into millwork's share of residential door installations have come chiefly from the wider use of steel for front and other exterior doors. In 1979, wood flush and panel doors accounted for 44 percent of all front door installations, compared with 68 percent in 1974 (the earliest year for which data are available). Displacement of wood by steel was similarly marked in the case of other exterior doors.[6] These tendencies have been somewhat offset by a slight but steady rise in recent years in the number of doors installed per dwelling.[7]

Whether industry output benefited from a continued shift from onsite carpentry of millwork items to factory production over the period cannot be readily determined. According to a BLS survey conducted in 1969, preassembled windows were installed in 78 percent of surveyed single-family houses built that year; and in 1968, prehung doors in 64 percent, and prefabricated staircase units in 25 percent.[8] No other such survey is available for the period examined here.

Window sashes and doors have been manufactured for more than a century, but most work was done onsite. Large-scale offsite production did not get underway until the 1930's and early 1940's, when a shift from onsite carpentry of millwork occurred.[9] Mass production of millwork was subsequently spurred by the large postwar demand for residential housing. Such product innovations as prehung doors (a door hinged on its frame, and delivered ready to be placed in the openings of the unit under construction) furthered the trend to factory production of items heretofore carpentered or finished at the site.[10] But no definitive data are available indicating the extent to which these developments raised the output of the millwork industry.

Employment increases moderately

Employment in the millwork industry, currently numbering 74,000 persons, rose at an average annual rate of 1.5 percent between 1958 and 1980. It peaked in 1978, when it stood 39 percent above the 1958 level. In general, it rose slightly during most of the 1960's, and more strongly in the early 1970's. Subsequent upswings and downswings were more marked than in earlier periods, reflecting similarly pronounced swings in the industry's output. Employee hours generally paralleled the trend in employment, rising at an average annual rate of 1.3 percent over the period. Average annual hours per employee in the millwork industry did not, on balance, change significantly between 1958 and 1972, and declined slightly between 1972 and 1980. Year-to-year changes were often larger for production worker employment than for production worker hours. The workweek per production worker averaged slightly less after 1972 (39.3 hours) than before (40.1 hours) indicating a drop in overtime. Generally, overtime averaged considerably less than for durables manufacturing as a whole.[11]

Differences in trend between production and nonproduction worker hours were not significant. But short-term fluctuations were much greater for production than for nonproduction worker employment and hours. The proportion of nonproduction workers, 18 percent in 1977, did not change materially over the study period, except for years of flagging industry output, when production worker employment weakened.

Industry employment evidences considerably higher turnover of production workers than durables manufacturing. In 1978, accessions (mostly new hires) in millwork, at 5.5 per 100 workers, were nearly two-fifths again as high as for all durables manufacturing; separations (mostly quits) were more than three-fifths again as high. High turnover rates mean a loss of trained and experienced workers[12] and more break-in periods required for newly hired workers, which may contribute to retarding productivity.

Technological developments

Millwork essentially consists of the sawing, shaping, planing, and sanding of wood to specified dimensions. The unfabricated lumber is delivered to the plant in the form of uniformly sized and quality-graded boards. Large-scale gluing operations are performed as part of the production process. Glazing is a normal part of the manufacture of windows and windowed doors.

Millwork is highly mechanized; virtually all work that transforms the lumber is done by machines. In some plants, feeding and tailing (the removal of the workpiece from the machine) are carried out manually, partly because of apprehension that a mechanized process would damage sensitive woods.

The basic technology used in millwork plants dates from the 1930's and 1940's when, as noted, large-scale production was first introduced in the industry. Factory production of millwork items antedates the 1930's, but large-scale operations were held back by the lack of waterproof, quick-curing adhesives. Moreover, millwork firms, at the time serving mostly local and regional markets, were slow in standardizing their product, hampering adoption by developers of housing projects. These obstacles began to be overcome with the innovation of synthetic resin adhesives, yielding waterproof bond.[13] Standardization progressed. Precision machinery became more widely available, probably accelerating the shift from onsite carpentry to the factory.[14] These developments also helped broaden the product lines of millwork firms. For example, complete double-hung windows mounted in prefabricated, weather-stripped frames, ready for installation at the construction site, were introduced in the 1940's and, subsequently, prehung doors.

Although the industry's basic machinery and equipment reflect woodworking technologies that have existed for many decades, there are indications that much of this equipment is less than 20 years old, and that sizable proportions are 10 years old or less.[15] Thus, three-fifths of the finger jointing machinery and of automatic mortisers appear to be in the lower age group, and as much as three-quarters of many types of sawing machinery. Fifty percent of door sizers, and much of the glue room equipment—including clamps and clamping machines, glue guns and pumps, and spreaders and presses—are of comparatively recent date, as is finishing equipment (for example, hot air ovens). The same holds for such general plant equipment as air conditioners, dust collectors, and computers. However, it cannot be determined from the available data whether the more recently installed—therefore, more up-to-date—equipment is well diffused throughout the industry. It is believed that diffusion is slow, partly because of the fragmentation of the industry into many firms.

A trend toward automated systems in the industry seems to be underway.[16] This trend is furthered by the declining costs of numerical controls, which more and more entail one-station systems featuring microcomputers.[17] That trend also involves computer-controlled material handling systems, robotized transfer and palletizing, and carousels interfacing with conveyors, robots, and other material handling devices.[18] But some persons in the industry argue that automation is unlikely to make much headway in millwork because it compels a financial commitment to highly specialized equipment—a commitment which often cannot be justified because of the erratic demand for the industry's products.

Other, more narrowly focused technological advances have been made which have evidently been more readily adopted than automated equipment. For example, the versatility of machines fabricating moldings has been greatly extended so that a large variety of complex molding profiles can be cut and grooved at great speeds without loss of precision and insignificant loss in setup time.[19] Ripsaws have been introduced whose sawing patterns can be controlled by instructions relayed by manipulating the shadow of an overhead wire. Stock which is free from knots and other flaws can thus be mechanically selected, eliminating a number of strenuous manual operations and resetting of the sawing machine, and reducing waste.[20] Solid-state sensing devices have in recent years been attached to abrasive planers, ensuring uniform surfaces. Abrasive planers were developed in an era of low-cost energy, but have become more energy-efficient, as well as faster.[21] Hand-operated sanders have been disappearing as multifunctional sanding machines have evolved. Thus, automatic thickness settings permit ranges from bites of ¼ inch to the finest surface finish.[22] A gradual shift from electrically powered to air-powered hand tools has probably also contributed to improving productivity. Air-driven hand tools are believed to achieve job requirements more efficiently, and to be less fatiguing for the operator because of their light weight and a wider choice of such options as handles and styles.[23]

Significant advances have likewise been made in adhesive applications. High-speed production requires rapid curing, and the gluing process is therefore usually an integral part of the production process. Certain radio frequency gluing devices have reduced curing time from 20 to 2 minutes, and, for example, as many as 20 door stiles can be processed at the same time. The saving in labor requirements made possible by this process has been estimated at 35 percent.[24] Bonding strength, too, has been increased, permitting the elimination of clamping in some operations (clamping has usually been regarded as a bottleneck in high-speed millwork assembly where gluing is required).[25]

Capital expenditures

New plant and equipment spending by the millwork industry went up fairly rapidly between 1963 (when pertinent data first became available) and 1978. In terms of constant dollars, it rose at an average annual rate of 4.7 percent.[26] However, the annual increase between 1963 and 1972, 9.4 percent, by far exceeded that for 1972 to 1978—1.2 percent. Significantly, outlays for buildings and other structures rose at nearly the same rate as for equipment during the former period, but declined during the latter. Capital spending by the industry showed at times huge year-to-year swings, induced most likely by fluctuations in demand for the industry's product from residential construction. Comparisons with trends in the private economy's fixed investment outlays follow (average annual rates of change, in percent).[27]

	1963–78	*1963–72*	*1972–78*
Millwork:			
Total	4.7	9.4	1.2
Machinery and equipment	6.3	10.3	0.9
Structures	1.6	8.1	-3.9
Private fixed investment:			
Total	3.6	4.6	2.4
Producer durable equipment	5.2	5.7	4.3
Nonresidential structures	0.9	3.1	-1.3

The tabulation shows that the pattern of vigorous capital spending growth in the 1960's and early 1970's in the millwork industry closely resembled that of the private domestic economy, and likewise that of meager capital spending growth in the mid-to-late 1970's. But for millwork, the slowdown was far more pronounced and spelled virtual stagnation in investment in new machinery and equipment.

New capital expenditures per employee in millwork represented only 42 percent of the comparable figure for manufacturing as a whole in 1978. That ratio does vary widely over time because of the large fluctuations of millwork firms' plant and equipment outlays (it was 61 percent in 1972). Yet, the comparative capital intensity of millwork is somewhat understated because its firms rent a larger proportion of plant structures and equipment than other manufacturers. In 1978, rents for structure represented the equivalent of 67 percent of millwork firms' purchases of structures, and rents for equipment, 22 percent. The corresponding figures for manufacturing were 34 percent and 9 percent. When rental payments are added to millwork's total capital outlays, the per-employee ratio to manufacturing mentioned above rises to 50 percent in 1978 (and 65 percent in 1972). That still spells relatively low capital intensity, a characteristic also manifest in the low value of the industry's fixed assets per employee—it represented between 42 and 44 percent of the manufacturing average in the 1970's. In 1976, each dollar of millwork shipments required 17 cents in fixed assets, compared with 34 cents for manufacturing in general.

Size of establishments

Millwork firms are preponderantly small—70 percent employed fewer than 20 workers in 1977, and another 23 percent employed from 20 to 99 workers. In this respect—that is, in terms of the size distribution of firms by employment—millwork closely resembles manufacturing. However, the smaller millwork establishments account for a much larger proportion of total employment in the industry than smaller manufacturing firms in general—50 versus 26 percent. The same pattern holds for the value of shipments, nearly one-half of which originated with the smaller millwork firms, compared with only about one-fifth for their counterparts in total manufacturing. Large millwork establishments—those employing 500 workers or more—recorded correspondingly smaller shares of total industry employment and shipments. The comparisons suggest that economies of scale are generally less of a factor of productivity improvement in millwork than in manufacturing.

LABOR PRODUCTIVITY IN MILLWORK should continue to advance moderately over the long term. The diffusion of automatic controls and the replacement of existing machinery with more up-to-date equipment will obviously be positive factors. But the predominance of smaller firms is likely to retard installation of automated transfer equipment, because, in their case, volume rarely justifies such equipment. Fluctuating residential building markets, and the trend toward apartment construction, will very likely continue to cause firms in the industry to be cautious in committing large funds to highly specialized automated machinery.

BLS employment projections have not been published for millwork alone, only for its industry group.[28] For it, a small, negative employment trend has been assumed during the 1980's. With demand from residential construction expected to expand, and industry employment to decline slightly, a moderate improvement in labor productivity is implied.[29] However, this progress is predicated upon the continued adoption of more advanced technologies by firms in the industry. □

FOOTNOTES

[1] The millwork industry has been designated as number 2431 in the 1972 Standard Industrial Classification Manual of the Office of Management and Budget. It consists of establishments which primarily manufacture such millwork products as moldings, wooden doors, windows, shutters, blinds, and awnings; and other architectural millwork items. All average annual rates of change are based on the linear least squares trend of the logarithms of the index numbers. The indexes for productivity and related variables will be updated annually and published in the annual BLS Bulletin, *Productivity Indexes for Selected Industries.*

[2] The data on average square foot are per single-unit dwelling, number of rooms and stories, and other examples mentioned in this and the following paragraph are from the following sources: *Characteristics of New One-Family Homes, 1968; Characteristics of New Family Housing: 1978*; both published by the Bureau of the Census, U.S. Department of Commerce, and U.S. Department of Housing and Urban Development, Washington, D.C.; James W. Myrtle, "Characteristics of New Housing," *Construction Review,* April 1979, pp. 4–9; Abraham Goldblatt, "Profile of New One-Family Homes," *Construction Review,* February 1973, pp. 4–8; and *Statistical Abstract of the United States, 1980* (Government Printing Office, 1980), p. 791.

[11] The majority of millwork production workers hold jobs as machine and materials handling operators and assemblers. *Industry Wage Survey: Millwork, June 1979,* Bulletin 2083 (Bureau of Labor Statistics, 1980).

[12] Some effects of high turnover rates are discussed by Peter Henle, "Economic Effects: Reviewing the Evidence," in Jerome M. Rosow *The Worker and the Job* (Englewood Cliffs, N.J., Prentice-Hall, 1974), p. 125.

[13] *Millwork,* p. 8.

[14] *Millwork,* p. 8. Hours worked by carpenters in building a 1-family dwelling have undoubtedly declined, and the decline in part points to a shift of the work conventionally performed by the carpenter to manufacturing. Thus, according to the BLS publication cited in footnote 8, there were 29 onsite carpenter hours required per 100 square feet of a 1-family house in 1969. According to studies done by the BLS for 1-family frame houses built in 1946–47, onsite carpentry then required

about 70 hours per 100 square feet. The decline implied in the number of onsite carpenter hours may have partly occurred because of differences in survey methods, the type of houses selected, and other technical or statistical factors. Moreover, part of the decline may be attributable to productivity improvements in carpentry. Nevertheless, a significant portion of the decline is likely to have been linked to shifts to factory production of carpentering work, including here millwork items, as well as roof trusses, plywood subflooring, and so forth. See Edward M. Gordon, "House Construction: Man-Hours by Occupation, 1946–47," *Monthly Labor Review*, December 1948, pp. 611–14; and Adela L. Stuckey, "Labor Share in Construction Costs of New Houses," *Monthly Labor Review*, May 1949, pp. 517–20.

[15] *An Inventory of Machines and Equipment in the Woodworking and Furniture Market*, issued by *Woodworking and Furniture Digest*, Wheaton, Ill., 1979. *An Inventory* presents the number of woodworking machines, by type, for each woodworking industry (as classified by the Standard Industrial Classification Manual). In a separate presentation, *An Inventory* shows the age breakdown of each type of woodworking machinery, but the age breakdown is not grouped by industry. The discussion in the text assumes that the age breakdown applies to machinery in the millwork industry where this industry accounts for a relatively large proportion of a given type of woodworking machinery. The authors of *An Inventory* believe this assumption to be valid.

APPENDIX: Measurement techniques and limitations

Indexes of output per employee hour measure changes in the relation between the output of an industry and employee hours expended on that output. An index of output per employee hour is derived by dividing an index of output by an index of industry employee hours.

The preferred output index for manufacturing industries would be obtained from data on quantities of the various goods produced by the industry, each weighted (multiplied) by the employee hours required to produce one unit of each good in a specified base period. Thus, those goods which require more labor time to produce are given more importance in the index.

In the absence of adequate physical quantity data, the output index for this industry was constructed by a deflated value technique. The value of shipments of the various product classes were adjusted for price changes by appropriate Producer Price Indexes to derive real output measures. These, in turn, were combined with employee hour weights to derive the overall output measure. The result is a final output index that is conceptually close to the preferred output measure.

Employment and employee hour indexes were derived from data published by the Bureau of the Census because BLS data were not available. Employees and employee hours are each considered homogeneous and additive, and thus do not reflect changes in the qualitative aspects of labor, such as skill and experience.

The indexes of output per employee hour do not measure any specific contributions, such as that of labor or capital. Rather, they reflect the joint effect of factors such as changes in technology, capital investment, capacity utilization, plant design and layout, skill and effort of the work force, managerial ability, and labor-management relations.

Research Summaries

The aging of the older population and the effect on its labor force rates

PHILIP L. RONES

Changes in labor force measures are not always easy to interpret. For instance, a rise in the unemployment rate over time is generally interpreted as meaning that it has become more difficult for an individual to find a job. But, that is not necessarily the case. The unemployment measure could show an increase over a long-term period even though the rates for each specific labor force group (by age, sex, and race) either remained stable or declined. This would occur if groups which typically have higher than average unemployment rates retained those rates as their proportion of the labor force increased. The increase in the aggregate measure, then, could stem from either a change in the age distribution of the population or changes in the labor force participation rates for specific groups.[1]

Probably the most widely used measure of the labor market status of older workers is not the unemployment rate but, rather, the labor force participation rate. This statistic has been closely followed in recent years because labor force activity of older workers affects social security and private pension outlays, and also could reflect the impact of mandatory retirement legislation. The participation rate for men age 55 and older has declined markedly in the post-World War II period, from 70.7 percent in 1948 to 44.5 percent in 1981, largely reflecting this group's improved financial ability to retire. During the same period, the participation rate for women age 55 and over rose from 17.2 to 22.7 percent, but that gain was far less than that registered by younger women.

In the last 2 years, a fall in participation rates for older persons of both sexes has accelerated, following 3 years of relatively slow decline. This has occurred despite changes in age discrimination laws and high rates of inflation, factors which many observers expected to provide upward pressure on participation. This recent labor force trend has spurred a rise in interest regarding the nature and causes of declining participation among older workers.

One possible explanation is that the fall in participation, particularly in recent years, might be partly the result of the aging of the older population. Basically, this is the converse of the argument that has been used to explain part of the rise in the unemployment rate. The rationale is that the oldest groups within the elderly population, those with the lowest participation rates, have been increasing as a proportion of the elderly and are receiving more weight in the overall calculation.

To examine the validity of this proposition, population and labor force data from the Current Population Survey (CPS) for men and women by single years of age were obtained for 1968, 1972, and 1981. Each year was selected for an important reason: 1968 is the first full year for which single-year-of-age data were tabulated using the civilian noninstitutional population concept; 1972 is the first year that the CPS used 1970-based population controls (rather than those projected from the 1960 census results); and 1981 is the most recent date for annual average data and also is the first year that 1980 census-based population estimates were available.

The census data themselves were not used because the single-year-of-age tabulations refer to *total* population, while the CPS, beginning in mid-1967, uses civilian *noninstitutional* population. This distinction is critical because of the rapid rise in the institutional population of the elderly (mostly in nursing homes), currently about 1.6 million people.

Analysis of the CPS data isolated the effects of three factors on changes in participation between 1968 and the two latter years (1972 and 1981). These were: (1) changes in the age-specific participation rates, (2) changes in the age composition of the population, and (3) changes attributable to "interaction", that is, changes that are not explained by the age-specific participation rates or by the age composition of the labor force. Interaction accounted for a very small portion of the total change in participation. Table 1 shows the amount of change accounted for by each of the three factors.

Philip L. Rones is an economist in the Division of Employment and Unemployment Analysis, Bureau of Labor Statistics.

Table 1. Changes in age components of labor force participation rates for men and women age 55 and older

Age and year	Average participation rate	Total change	Change due to —		
			Age specific participation rate	Age composition of population	Inter-action effect[1]
Men, age 55 and over:					
1968	56.54	0.00	0.00	0.00	0.00
1972	53.36	-3.18	-3.33	.19	-.04
1981	44.47	-12.07	-11.28	-.71	-.08
Age 55 to 64:					
1968	84.26	0.00	0.00	0.00	0.00
1972	80.51	-3.75	-3.51	-.21	-.03
1981	70.63	-13.62	-13.31	-.21	-.10
Age 65 and over:					
1968	27.27	0.00	0.00	0.00	0.00
1972	24.35	-2.92	-3.13	.27	-.06
1981	18.35	-8.92	-9.15	.37	-.14
Women, age 55 and over:					
1968	25.04	0.00	0.00	0.00	0.00
1972	24.52	-.52	-.19	-.33	.00
1981	22.73	-2.31	-1.14	-1.13	-.04
Age 55 to 64:					
1968	42.44	0.00	0.00	0.00	0.00
1972	42.14	-.30	-.16	-.15	.01
1981	41.35	-1.09	-.83	-.19	-.07
Age 65 and over:					
1968	9.57	0.00	0.00	0.00	0.00
1972	9.33	-.22	-.20	-.03	.01
1981	8.01	-1.56	-1.41	-.16	.01

[1] The "interaction" effect is that part of the total change in participation not explained by the other two variables.

The amount of change in participation attributable to changes in age-specific participation rates is derived by first computing participation rates for single-years-of-age between age 55 and 74 and for age 75 and over. Then, a rate was computed using the following formula (1981 is the target year and 1968 is the base year):

$$\frac{\Sigma_i (r_{i81} \cdot pop_{i68})}{\Sigma_i pop_{i68}}$$

where:

> r_{i81} is the 1981 participation rate for the ith age group and pop_{i68} is the 1968 civilian noninstitutional population for the ith age group.

Simply put, this calculation shows what the participation rate would have been in 1981 if the population distribution had been the same as in 1968. In other words, it isolates the effect of changing participation rates. For instance, for men age 55 and over, changing participation accounted for 11.28 points of the fall in participation between 1968 and 1981; therefore, their adjusted 1981 rate is 45.26 percent (56.54–11.28).

The formula used to compute the effect of changes in the population distribution is:

$$\frac{\Sigma_i (r_{i68} \cdot pop_{i81})}{\Sigma_i pop_{i81}}$$

where:

> r_{i68} is the 1968 participation rate for the ith age group and pop_{i81} is the 1981 civilian noninstitutional population for the ith age group.

This calculation shows what the rates would have been in 1981 if the age-specific participation rates had remained as they were in 1968. In other words, it isolates the impact of changes in the age composition of the population. For men age 55 and over, the adjusted participation rate in 1981 was 55.83 percent, explaining only .71 point of the 12.07-point fall in participation since 1968.

Results

Among men, the change in the age structure of the 55-and-over population has had relatively little impact on the dramatic declines in participation. In fact, for men age 65 and over, the changing population distribution caused a slight rise in participation rates, indicating that the growth has been greater in the younger, not older, groups in this age cohort. The following tabulation of age distribution for men age 65 and over in 1968 and 1981 demonstrates this:

	Percent of population in—	
	1968	*1981*
65 and over	100.0	100.0
65	8.4	8.3
66	7.8	8.4
67	7.6	7.8
68	7.3	7.3
69	6.2	6.5
70	6.2	6.5
71	5.5	5.9
72	5.4	5.6
73	5.4	5.3
74	4.7	5.0
75 and over	35.4	33.5

The oldest age group, age 75 and over, made up a much larger proportion of all men age 65 and older in 1968, while the younger age groups predominated in 1981. The 55-to-64 group did age somewhat over the 18-year period, but only enough to explain about two-tenths of a point out of a participation rate decline that, by 1981, totaled more than 15 points.

Unlike the mixed results experienced by men, the age composition effect was consistently in the downward direction for older women.[2] For women ages 55 to 64 and 65 and over, the age effect was less than two-tenths of a point in both 1972 and 1981. The relatively large age effect, by 1981, in the 55-and-over group suggests a shift in population into the older (65 and over) age group. (A similar shift, causing a .71-point decline in participation, occurred among men.) However, the participation rates for older women have changed comparatively little over time and tend to be much less an issue than those for men, which have fallen dramatically. In the years ahead, the aging of the first generation of American women who have developed a strong labor force attachment is likely to provide upward pressure on the participation rates of women age 55 and over.

The declines in participation among older workers over the last several years are particularly noteworthy, because they occurred despite increased protection against forced retirement and the prevailing high rates of inflation. The main causes of the long-term declines in participation among the elderly have been documented,[3] and the declines in the last 2 years may have been intensified by the weakening economy. The changing age distribution of the older population seems to have played, at most, a very small part in these important labor force trends. □

——*FOOTNOTES*——

[1] The effect of these influences on the unemployment rate was discussed in a series of articles in the March 1979 *Monthly Labor Review*. See Paul O. Flaim, "The effect of demographic changes on the Nation's unemployment rate"; Glen G. Cain, "The unemployment rate as an economic indicator"; and Joseph Antos and others, "What is a current equivalent to unemployment rates of the past?"

[2] It should be kept in mind that the "aging" of the older population is limited by the use of the noninstitutional population in the calculations. Nursing home residents, who make up most of the institutional elderly, are concentrated in the oldest age groups and the vast majority are women.

[3] See, for example, Philip L. Rones, "Older men—the choice between work and retirement," *Monthly Labor Review*, November 1978, pp. 3–10; or Joseph F. Quinn, *The Microeconomics of Early Retirement: A Cross Sectional View* (U.S. Department of Health, Education, and Welfare, 1975).

Occupational changes and tenure, 1981

Nancy F. Rytina

The labor force is characterized by a relatively high degree of occupational change. Studies have shown that most workers are employed in occupations which differ from those of their fathers.[1] Occupational shifts are also quite common over the course of a worker's career. The occupation held by a worker in midlife often differs from the first occupation after leaving school.[2]

Although the volume of occupational mobility that occurs within a given year is much smaller, it provides an indication, on a current basis, of recent trends. When assembled over time, data on 1-year mobility shows changes that are important for purposes of developing vocational and higher educational programs.

Studies of 1-year occupational mobility based on data from the Current Population Survey (CPS) of January 1966, 1973, and 1978 indicated that about 1 in 10 of all workers in each year were employed in a different occupation than in the previous year.[3] Much of the occupational change was concentrated among persons under age 30 who tend to "job shop" as they obtain exposure to various kinds of work.

This report presents an update of these previous studies. The data shown are based on information obtained in the January 1981 Current Population Survey and relate to the occupations of workers in that month and in January 1980. Workers who changed occupations are defined as those employed in both January 1980 and January 1981, but in a different "three-digit" census occupation in January 1981 than the occupation reported for January 1980. For example, a person employed as a typist in 1981 and as a stenographer in 1980 would be defined as having changed occupations, although the change occurred within the major occupational grouping—clerical workers. The occupational mobility rate used in this report refers to the number of workers who changed occupations as a proportion of the total number employed in January of 1980 and 1981.[4]

This study also presents new information on occupational tenure based on the years spent in the current occupation. These data are limited to persons employed in both January 1980 and 1981. Workers in the same "three-digit" census occupation in January 1981 as in January 1980 were asked how many years, altogether, they had "been doing that kind of work." Persons who had changed occupations were assigned to the tenure category of less than 1 year.

The data on both occupational mobility and tenure are subject to a number of limitations. Besides those normally associated with sample surveys (sampling variability and nonresponse), there may be errors associated with the retrospective reporting of the occupation a year earlier and the number of years in the same occupation.[5] Because occupation is reported only for the months of January 1980 and January 1981, any temporary changes in occupation that occurred during the year will not be reflected in the survey results. Since the tenure question was asked only of persons in the same occupation in January 1980 and 1981, the tenure data exclude persons employed in January 1981 but not January 1980, as well as any years spent in the occupation prior to 1980 for persons not in the same occupation in both January 1980 and 1981. Moreover, the information on tenure was collected in a combination of single and multiyear intervals, thus making it difficult to obtain reliable estimates of mean or median tenure.[6]

Nancy F. Rytina is a demographer in the Division of Labor Force Studies, Bureau of Labor Statistics.

Workers who changed occupations

Of the 88.3 million employed workers 18 years of age and over and not in school in January 1981, 9.5 percent reported employment in a different occupation in January 1980. Eighty-one percent had been in the same occupation and the remaining 9 percent had either been unemployed or not in the labor force the previous January. The occupational mobility rate stood at 10.5 percent. Both the distribution of labor force status in the previous year and the mobility rate are not much different from the CPS data reported for 1966, 1973, and 1978.

In 1981, as in earlier years, age was the factor most associated with occupational change. Of the total 8.4 million workers who shifted occupations between January 1980 and January 1981, 70 percent were under age 35, although this age group accounted for only 46 percent of the labor force in January 1981.

Not surprisingly, occupational mobility rates declined sharply with age (table 1). The rate for workers age 35 to 44 was less than one-fourth as high as that for workers 18 and 19 years of age. High rates of occupational mobility among young workers are accounted for by a number of factors. Upon completion of school, young persons often try several fields of employment before settling into a career. Also, as many of them make changes in residence and living arrangements, they also change occupations. In contrast, occupational change among older workers occurs less frequently because of attachments to a particular occupation or the risks of losing income, job security, and pension rights, which might accompany an occupational shift.

Mobility rates by age were much the same as in the earlier CPS surveys. Standardizing the mobility rates by age in 1966 and 1981 suggests that the slightly higher rate observed in 1981 (10.5 versus 8.8) was almost entirely a result of the increased proportion of young persons in the work force.[7]

Differences in occupational mobility by sex are quite small relative to age differences. For both men and women, mobility rates decreased with age (table 1). Women, however, have a slightly higher mobility rate than men (11.4 versus 9.9 percent). Since 1966, the mobility rate for women has risen substantially, up from 6.6 percent. An increase is to be expected because of the entry into the labor force of women from younger age groups which have always had higher mobility rates. However, standardizing for age indicates that over 70 percent of the increase was attributable to changes in mobility within specific age groups.[8] The rise in the rate of occupational change for women reflects their shift into professional and managerial occupations as well as their increased employment in clerical jobs where the rate of occupational change has traditionally been high. In contrast, the mobility rate for men in 1981 was at the same level as in 1966. The 1981 male rate, however, probably would have been slightly lower were it not for the increase in the proportion of young men in the labor force.

Occupational mobility rates do not differ much by race and ethnicity. Among men, the rate is slightly higher among Hispanics partly because they are younger than either whites or blacks. The rate for white women is higher than that for either black or Hispanic women and this difference is evident among most age groups.

The reason given for changing one's occupation is one factor which is not strongly related to age (table 2). Close to 43 percent of all workers reported better pay as the most important reason for shifting occupations.[9] Better pay is cited more frequently than any other reason among all age, sex, race, and ethnic groups except workers ages 55 and over. A larger percentage of older workers cited "other" reasons (presumably retirement from the previous occupation) than better pay. The recession of 1980 may have some bearing on the fact that

Table 1. Occupational mobility between January 1980 and January 1981 of employed persons, by age, sex, race, and Hispanic origin, January 1981

Characteristic	Total employed in January 1981		Status in January 1980				Occupational mobility rate[1]

nearly 11 percent of all workers cited either job loss or layoff as the reason for changing occupations.

In addition, the length of time spent with the current employer is closely associated with occupational mobility. About 90 percent of all workers who changed occupations had less than a year of tenure with their current employer, compared with 10 percent of all workers who remained in the same occupation. (See article on job tenure, page 34.)

An indication of how mobility rates varied by the occupation of the employed in 1981 is provided in table 3. For both sexes, mobility rates are generally highest in those occupations with large percentages of young workers. For example, nonfarm laborers have a high mobility rate and over 50 percent of all workers moving into that occupation were under age 25. Similarly, large percentages of young workers shifted into the clerical and service occupations. An exception is the high mobility rate for women employed as managers. Almost one-fourth of women moving into this occupation were 35 to 44 years of age, in part reflecting an expansion in employment opportunities for women in management.

Some of the occupations with lower rates of mobility are those requiring high levels of education (professional) or other specialized training (craft). Declining employment opportunities in farming and the attachment to the land of those who have remained in this occupation explain the very low mobility rates for farmers and farm managers.

Evidence regarding the occupational origins and destinations of workers who changed occupations is provided in table 4, which shows the occupational distribution in January 1980 for each occupation in January 1981. It is apparent that workers who changed occupations came largely from the same occupational grouping, that is, from related occupations. For example, among professionals, 43 percent of the men and 37 percent of women had been employed in a professional occupation in January 1980. The degree of intraoccupational group shifting was also quite high for men employed as managers, craftworkers, and operatives, except transportation equipment operatives. For women, intraoccupational group shifting was particularly high among clerical workers, operatives (except transportation equipment operatives), and service workers. About

Table 3. Occupational mobility rates between January 1980 and January 1981 of employed persons, by occupation and sex

[Numbers in thousands]

[2] Data not shown where base is less than 75,000.

60 percent of women in clerical work in January 1981 had come from that occupational group. This results partly from the high degree of skill interchangeability and employment turnover that occurs within clerical occupations.

Also, most of the shifts between occupational groupings tended to occur within the same broad fields, for example, white-collar and blue-collar occupations. About 80 percent of women and 66 percent of men employed in white-collar occupations had been employed in these occupations during the previous year. Similarly, over 70 percent of men in blue-collar occupations were employed in the same occupations a year earlier. In contrast, the proportion of women employed in blue-collar occupations is comparatively low. Not surprisingly, about one-half of women who shifted into blue-collar occupations came from the white-collar and service occupations.

Occupational tenure

An indication of occupational tenure is found by examining the distribution of the number of years spent in the January 1981 occupation for those who had been in the same occupation in January 1980. It should be noted that because the data on occupational tenure in this report are restricted to persons employed in January 1980 and January 1981, the occupational mobility rates shown in previous tables are equivalent to the proportion of workers with less than 1 year in the occupation.

Of the 80 million workers employed in both January 1980 and 1981, over one-third had been in the same occupation from 1 to 5 years (table 5). Adding to that figure those in the occupation less than 1 year indicates that close to one-half of all workers had been employed in their January 1981 occupation less than 5 years.

Tenure in the occupation is strongly linked with age.

Table 4. Persons who changed occupation: major occupational group in January 1981, by occupation in January 1980

55 years and over	12,757	100.0	2.9	16.5	13.9	33.9	32.9

¹ Rounds to zero.

Workers under age 35 were concentrated in the 1 to 5 years category, while the majority of workers age 35 and over had been in the same occupation 5 years or more.

Men had more years in the same occupation than women. The sex difference is especially pronounced at 10 years or more in the occupation. Although women have continued to gain on men in year-round employment, they experience greater job turnover. This stems partly from personal and family priorities, but also because women have remained segregated in occupations which have high rates of turnover.

In terms of race and ethnicity, the distribution of occupational tenure is relatively similar between blacks and whites compared to Hispanics. Among blacks and whites, approximately 50 percent were in the same occupation for less than 5 years, compared to almost 60 percent among Hispanics. The lower occupational tenure of Hispanics can be attributed to some degree to their lower average age and greater likelihood of employment in service, laborer, and farm occupations.

The number of years in the same occupation varied by the January 1981 occupation. Much like the incidence of occupational change, tenure of less than 5 years is more common in occupations requiring less training (operatives and laborers), transferable skills (clerical work), or high employment growth (managers for women). In contrast, tenure is relatively high in occupations with either declining employment opportunites (farmers and farm managers) or where specialized skills and lengthy training are involved (professionals for both sexes and craftworkers for men).

This report has provided an update on patterns of occupational change between 1980 and 1981 and described the distribution of occupational tenure among various demographic groups. With the January 1981 CPS, it is also possible to examine how occupational change and tenure relate more specifically to the economic status of workers. For example, the occupational categories used here were broad and conceal sex, race, and ethnic differences in employment that might be uncovered by focusing on detailed occupations. In terms of earnings, findings from a recent study using these data suggest that the lower tenure of women accounts for just 4 percent of the male-female earnings gap.[10] The January 1981 CPS data can be used to explore further these and other labor force topics. ☐

[3] For reports using earlier CPS data see Samuel Saben, "Occupational mobility of employed workers" (January 1965–66), *Monthly Labor Review*, June 1967, pp. 31–38, reprinted as Special Labor Force Report 84; James J. Byrne, "Occupational mobility of workers" (January 1972–73), *Monthly Labor Review*, February 1975, pp. 53–59, reprinted as Special Labor Force Report 186; and Carl Rosenfeld, "Occupational mobility during 1977" (January 1977–78), *Monthly Labor Review*, December 1979, pp. 44–48, reprinted as Special Labor Force Report 231.

[4] This rate measures the proportion of workers who entered the occupation, not the proportion leaving the occupation held in 1980. This is only one of a number of possible measures of mobility, and it was selected because it is the same measure used in the previous studies. See footnote 3.

[5] See Paula J. Schneider, "Evaluation of the Occupation One-Year Ago Item in the January 1973 CPS," *Proceedings of the Social Statistics Session of the American Statistical Association*, 1977.

[6] The categories included 1 up to 2 years, 2 up to 3 years, 3 up to 4 years, 4 up to 5 years, 5 up to 10 years, 10 up to 25 years, and 25 years or more.

[7] The 1981 mobility rates by age were standardized on the 1966 age distribution resulting in a standardized mobility rate of 9.3. Reversing the procedure, the 1966 mobility rates by age were standardized on the 1981 age distribution which resulted in a standardized mobility rate of 10.8. The average of the "rate effect" and the "age effect" shows that 97 percent of the difference between the reported mobility rates of 8.8 in 1966 and 10.5 in 1981 was due to differences in the age distributions in the 2 years. See Evelyn M. Kitagawa, "Components of the Difference Between Two Rates," *Journal of the American Statistical Association*, December 1955, pp. 1168–94. Other standardization techniques are discussed in Henry S. Shryock and Joseph Siegel, *The Methods and Materials of Demography, Vols. I and II* (Bureau of the Census, 1971). Another possible source of difference between the 1966 and 1981 rates is that there were fewer three-digit occupations listed in the 1966 CPS.

[8] Based on age standardization. See footnote 5.

[9] This category also includes changing occupations for advancement opportunities and full-time work.

[10] See Nancy F. Rytina, "Tenure as a factor in the male-female earnings gap," *Monthly Labor Review*, April 1982, pp. 32–34.

Job tenure of workers in January 1981

FRANCIS W. HORVATH

Close to 30 percent of all workers during January 1981 had been on their jobs less than 1 year. At the same time, however, nearly one-fourth had been at the same job more than 10 years. (See table 1.) Overall, the median job tenure was 3.2 years.

This report gives the most recent summary statistics on job tenure derived from a special supplement to the January 1981 Current Population Survey and reviews some basic relationships in the data.[1]

Job tenure is a measure of the length of time an employee has worked continuously for the same employer, although not necessarily in the same occupation; continuous employment is broken only by interruptions other than vacations, temporary illnesses, strikes, layoffs of less than 30 days, or other short-term absences. A person terminates his or her tenure by quitting, being laid off for 30 days or more, entering the Armed Forces, or transferring to a job in a different company.

Measurement of job tenure is affected by many of the same methodological issues which complicate other time-based indices such as unemployment duration. Just as the average duration of unemployment is not a measure of how long a person is likely to remain unemployed,[2] job tenure is *not* a measure of how long a person will stay with a single employer. Rather, it is an index of how long one has been with an employer as of a specific point in time. This is an important distinction, which may be illustrated by comparing the average age of a population with its life expectancy. The average age tells nothing about completed life spans; it measures only the age of those who are still living. Similarly, job tenure is an index of accumulated time on the job for those still working.

Job tenure should not be confused with occupational mobility (discussed in more detail on page 29): Job tenure is a duration concept. On the other hand, occupational mobility pertains to persons who change occupations but not necessarily employers. Also, occupational mobility is more frequently discussed in terms of rates of change, while job tenure is usually presented as a length of time.

Job tenure is influenced by both voluntary and involuntary choices. For example, the part-time and summer jobs of most young persons are not intended to be permanent. For others, especially those who work in industries such as construction or retail trade, regular cycles of expansion and contraction in employment can reduce the length of one's tenure.

Table 1. Length of time on current job, workers 16 years and older, by sex, race, and Hispanic origin, January 1981

[Numbers in thousands]

Length of time on current job	Both sexes	Men	Women	White	Black	Hispanic origin
Total: Number	92,557	52,700	39,857	82,375	8,514	4,734
Percent	100.0	100.0	100.0	100.0	100.0	100.0
6 months or less	18.2	15.9	21.4	18.3	17.5	23.2
7 to 12 months	9.5	8.9	10.4	9.6	8.6	11.3
Over 1 to 2 years	11.6	10.3	13.3	11.5	11.4	13.6
Over 2 to 3 years	9.2	8.6	9.9	9.2	8.9	10.0
Over 3 to 5 years	12.0	11.5	12.6	12.0	11.4	13.3
Over 5 to 10 years	15.9	16.2	15.6	15.7	18.2	14.5
Over 10 to 15 years	9.6	10.4	8.4	9.4	11.5	7.6
Over 15 to 20 years	5.3	6.4	3.9	5.4	5.4	3.0
Over 20 to 25 years	3.4	4.4	2.2	3.5	2.9	2.0
Over 25 to 30 years	2.4	3.3	1.3	2.5	2.4	.9
Over 30 to 35 years	1.7	2.5	.7	1.8	1.2	.4
Over 35 years	1.2	1.7	.5	1.2	.6	.2
Median years	3.2	4.0	2.5	3.2	3.6	2.2

With the termination of the BLS Labor Turnover Survey because of budget reductions, job tenure information has become an important official data source relating to labor turnover. Even though the tenure survey is conducted only every 3 to 5 years, it provides valuable insights into the magnitude of job turnover and stability in the economy.

Job tenure data can also be combined with mortality projections to provide estimates of the proportion of workers who will remain on the job for a specified number of years. For example, the data may be used to estimate how many of a company's current employees might be eligible to receive future benefits under existing pension provisions.[3]

Not surprisingly, young workers have the lowest levels of job tenure. Fifty percent of all teenagers working in January 1981 had been at their jobs for 6 months or less. Almost 70 percent had started their jobs within

Table 2. Median years on current job, by age, race, and Hispanic origin, and sex, January 1981

Age	All workers			White		Black		Hispanic origin	
	Both sexes	Men	Women	Men	Women	Men	Women	Men	Women
Total, 16 years old and over	3.2	4.0	2.5	4.0	2.4	4.0	3.3	2.3	2.0
16 to 24 years	.8	.9	.8	.9	.8	.7	.8	.9	.9
25 to 34 years	2.5	2.9	2.0	2.9	2.0	3.0	2.7	2.4	1.9
35 to 44 years	4.9	6.6	3.5	6.7	3.3	6.2	5.2	3.7	3.2
45 to 54 years	8.4	11.0	5.9	11.2	5.7	10.0	8.1	6.4	4.4
55 to 64 years	11.9	14.8	9.1	14.9	9.1	14.4	10.3	8.6	5.8
65 years and older	10.2	10.3	10.0	10.1	9.8	12.0	11.9	(1)	(1)

[1] Median not shown where base is less than 75,000.

Francis W. Horvath is an economist in the Division of Labor Force Studies, Bureau of Labor Statistics.

Table 3. Median years on current job, by age, marital status, and sex, January 1981

Age	Single		Married, spouse present		Other marital status[1]	
	Men	Women	Men	Women	Men	Women
Total, 16 years old and over	1.2	1.2	6.0	3.1	4.3	3.4
16 to 24 years	.8	.7	1.2	.9	1.0	.8
25 to 34 years	2.2	2.4	3.2	2.0	2.4	1.7
35 to 44 years	4.7	6.1	6.8	3.4	5.2	3.1
45 to 54 years	10.5	10.9	11.5	6.2	8.7	4.7
55 to 64 years	16.2	14.3	15.1	9.4	10.7	8.2
65 years and older	([2])	10.7	10.3	9.8	10.9	10.0

[1] Includes widowed, divorced, and separated persons.

[2] Median not shown where base is less than 75,000.

the previous year. In addition to the higher exposure to layoffs or terminations that teenagers face, they are more likely to be working in temporary jobs by choice, as they attend school or sift through various jobs in search of a suitable career. Even when teenagers hold jobs that are career-oriented, their careers do not begin until formal schooling or military service is completed.

For all demographic groups shown (except men over 65 years old) successively higher age intervals show greater levels of job tenure. (See table 2.) The highest medians occur for men age 55 to 64—exceeding 14 years. Approximately 30 percent of men in this group have served the same employer for more than 25 years. At the other extreme, a basic rate of job changing seems to occur at every age level: close to 9 percent or more of the workers of all age groups with jobs in January 1981 had started them within the past year.

Men have higher overall median levels of tenure than women, 4 years compared with 2.5. (See table 2.) Part of this difference is because of the greater proportion of working women who are under age 25. Another factor is the greater likelihood of women leaving jobs to care for young children. Sharp male-female contrasts in tenure by age do not appear until after the women's prime childbearing years.

Overall, black workers had more years of job tenure than whites did in 1981. (See table 1.) White and black men had identical median job tenure of 4 years, but black women had worked longer than white women. (See table 2.) This difference may be related to the work patterns of those of childbearing age. White women with children under age 6 were less likely to be working than black women, and significantly fewer of the former were employed full time.[4]

Job tenure differences between sexes of the same race were also observed. (See table 2.) For whites, men had the longer tenure regardless of age. The largest relative difference in medians for white men and women occurred in the 35-to-44-year age group, where the female median was only about half that of men. Among blacks, both sexes showed only slight dissimilarities in tenure from the teens to middle age; the largest difference was found among those age 55 to 64.

The inhibiting effect young children have on the worklives of wives may help account for differences in job tenure by marital status. (See table 3.) While single men and women had small relative differences in years on the job, wives had far fewer years than husbands.

Because single persons tend to be young, the typical single man or woman has accumulated a limited number of years on their current job. The median level of job tenure for both single men and women is 1.2 years, compared with about 3.1 for wives and 6 years for husbands. At most age levels below age 54, husbands have more years on the job than single men, while wives have fewer years than their single counterparts.

Firms in growing industries usually hire new persons as they expand, and these industries will thus show correspondingly low levels of job tenure. Other establishments, in areas which are stagnant or declining, do not hire as often, letting positions expire as they become vacant. If a reduction in personnel is required, it will generally be concentrated among persons with the least seniority. Each of these actions increases the observed job tenure among those still in the industry.

Table 4. Median years on current job, by occupation, industry, and sex, January 1981

Occupation and industry	Men	Women
Total, all workers	4.0	2.5
OCCUPATION		
Professional, technical, and kindred workers	4.9	3.1
Managers and administrators, except farm	5.7	3.3
Salesworkers	3.4	1.7
Clerical and kindred workers	3.4	2.4
Craft and kindred workers	4.4	3.4
Operatives, except transport	3.5	3.1
Transport equipment operatives	3.7	3.1
Nonfarm laborers	1.8	1.9
Service workers	2.1	1.8
Farmers and farm managers	17.5	9.9
Farm laborers and supervisors	2.3	4.1
INDUSTRY		
Agriculture	7.3	4.4
Wage and salary workers	2.3	1.5
Self-employed workers	16.3	8.1
Unpaid family workers	5.2	13.3
Nonagricultural industries	3.9	2.5
Wage and salary workers	3.7	2.4
Mining	2.6	—
Construction	2.4	2.1
Manufacturing	5.2	3.2
Transportation and public utilities	5.6	3.5
Wholesale and retail trade	2.2	1.5
Finance, insurance, and real estate	4.1	2.3
Service	3.1	2.6
Public administration	6.8	3.0
Self-employed workers	8.2	3.4
Unpaid family workers	([1])	5.7

[1] Median not shown were base is less than 75,000.

Note: Dashes indicate data not available.

Table 5. Median years on current job of women by age, marital status, and full- and part-time status, January 1981

Age	Single		Married, spouse present		Other marital status[1]	
	Full time	Part time	Full time	Part time	Full time	Part time
Total, 16 years old and over	1.6	0.6	3.4	2.3	3.4	3.6
16 to 24 years	.8	.5	1.0	.5	.8	(2)
25 to 34 years	2.6	.9	2.4	1.2	1.7	1.2
35 to 44 years	6.2	(2)	3.8	2.4	3.2	2.3
45 to 54 years	11.9	(2)	6.7	4.8	4.6	3.8
55 to 64 years	15.3	(2)	10.7	5.8	8.7	5.5
65 years and older	(2)	(2)	11.5	7.4	11.3	8.5

[1] Includes widowed, divorced, and separated persons.
[2] Median not shown where base is less than 75,000.

In addition, job tenure will also be influenced by skill level of the work force. Employers are less likely to lay off or fire skilled workers, as it costs more in hiring and training costs to replace them.[5] Employers may try to reduce voluntary terminations of more valuable employees by linking vacation or pension benefits to increased seniority.

By industry, self-employed men in agriculture had the longest spells of job tenure. Self-employed workers in nonagricultural industries also had a high level of job tenure, although male wage and salary workers in public administration ranked highest. (See table 4.)

Since 1963, surveys have found farmers to have the longest job tenure of any occupational group. They tend to own their own farms, and remain at work regardless of cyclical fluctuations. In January 1981, median job tenure for male farmers was 17.5 years, well above that of all other occupations. Managers and administrators have the next highest level of job tenure for men, followed by professional workers. Laborers—both farm and nonfarm—have the lowest tenure on their current job. For women, the patterns by occupation are similar except farm laborers have relatively high tenure; probably these women work on family farms owned or operated by their husbands.

Tabulations of years of tenure were also compiled by full- or part-time status on one's current job. In general, part-time workers had less job tenure than full-time ones. A typical pattern is displayed in table 5, which lists job tenure for women by full- and part-time status.

For women who are widowed, divorced, or separated, relatively little difference by job status is apparent, but for wives, part-time work on the current job correlates with fewer years of tenure. Again, it seems likely that a desire to rearrange work schedules to facilitate child care is a major factor behind the relationship. ☐

———*FOOTNOTES*———

[1] This report is based primarily on information from a supplementary question, "When did . . . start working at his present job or business?" in the January 1981 Current Population Survey, conducted by the Bureau of the Census for the Bureau of Labor Statistics. Most of the data relate to persons who are 16 years old and over employed in the civilian labor force in the week ending January 17, 1981. Sampling variability may be large where numbers are small. Therefore, small differences between estimates or percentages should be interpreted with caution.

Employment figures in this study differ significantly from those reported in the regular Current Population Survey (CPS) for January 1981. The primary reason for this difference is that the job tenure data are not adjusted for nonresponse as are the CPS figures. See *The Current Population Survey: Design and Methodology*, Technical Paper No. 40 (U.S. Department of Commerce, 1978), for more information.

This is the seventh in a series of reports on this subject. The latest contained data for January 1978 and appeared in the December 1979 *Monthly Labor Review*. It was reprinted with additional tabular data and an explanatory note as *Special Labor Force Report 235*, "Job Tenure Declines as Work Force Changes." There are no comparisons in this report between 1978 and 1981 median tenure data, because of a change in the procedure used to calculate the medians. The 1981 Job Tenure Survey obtained more detail than earlier ones about persons who had begun their jobs during the previous year. Such people were asked the *month* in which they started work with their present employers. Additional information can be obtained from the Division of Labor Force Studies.

[2] Norman Bowers, "Probing the issues of unemployment duration," *Monthly Labor Review*, July 1980, pp. 23–32.

[3] "Job Tenure of Workers, January 1973," *Special Labor Force Report 172* provided an example of how this might be done.

How European unions cope with new technology

STEVE EARLY AND MATT WITT

In European countries, as in the United States, computerized production systems and robots are being introduced into manufacturing plants. Electronic systems are eliminating many tasks for which workers previously were needed in warehouses, stores, banks, and insurance companies. Many secretaries, government workers, reporters, telephone operators, engineers, and technicians are working at electronic screens called video display terminals. Such changes threaten job security and could make the jobs which remain less interesting, more isolated and stressful.

Matt Witt is director and Steve Early, a former staff member, of the American Labor Education Center, Washington, D.C. Research for this report was supported by the German Marshall Fund of the United States.

European unions generally are not trying to block technological change; rather they want to be sure such change will benefit workers as well as employers. To do this, the unions are asking for: consultation before decisions are made about new technology; technology which increases rather than replaces the workers' traditional skills, and which improves rather than worsens working conditions; protection from job losses and lower pay rates; a share in the profits and social benefits created by new technology; and assurance that new technology will not be used to undermine the union. To achieve these goals, they are giving local union committees more information and power.

By using their powerful labor parties to influence government policy, European unions have already won some new rights through legislation. For example, in Norway and Sweden, unions have the legal right to complete information about proposed new technology. Union representatives attend meetings of company boards of directors, obtain all information available to those boards, and present the union's point of view. Also, national "work environment" laws give unions the power to veto workplace changes which would adversely affect job safety and health, as many new technologies do without proper design and planning.

Through collective bargaining, European unions have won additional rights. For instance, a branch of the Norwegian Iron and Metal Workers' Union, which represents blue-collar and white-collar workers at an International Telephone and Telegraph subsidiary, has won the contract right to block any new computerized system that does not meet its approval.

In Germany, a contract covering about one-third of the metal workers guarantees against a decrease in income because of changing work assignments caused by new technology. And, at American Express, which employs 1,200 workers in banks on U.S. military bases, the German banking union won a contract prohibiting involuntary layoff or transfer of workers as a result of technological change.

A new technology benefit for Civil Service unions representing 600,000 government workers in England included a 10-percent reduction in working hours.

Another benefit, bargained by many unions in Norway, Sweden, and England, provides video display terminal operators with a 4-hour per day limit on their machines—scheduled in 2 hours on, 2 hours off rotation. This system forces employers to arrange a variety of work assignments for clericals who would otherwise be restricted to their terminals.

European unions are aided in preparing bargaining proposals by knowledge gained in union-sponsored, employer-financed training programs on new technology. Unlike U.S. unions which foot the bill for most labor education, national laws in Europe require management to pay stewards, local officers, and committee members for attending union classes.

In Sweden, Germany, Norway, and England, unions have also obtained millions of dollars in government or employer funds to pay for training courses in the new technology.

In Scandinavia, the money for training comes from national work environment or labor education funds, financed by employer contributions largely controlled by the labor movement. In West Germany and Great Britain, union training programs are subsidized by government departments of industry, research, or technology.

European unions also have obtained government or employer funds to consult with outside experts on new technology. Many unions in Norway, Sweden, and Great Britain get advice from labor-oriented computer experts from university research programs and technical institutes, such as the government-funded Norwegian Computing Center, Swedish Work Life Center, and the British Center for Alternative Industrial Technological Systems. Under a government grant, the German Metal Workers set up a national system of "innovation advice bureaus" consisting of engineers, economists, and other technicians, to help local unions evaluate and bargain over employers' new technology plans.

German unions have also been represented for several years on advisory committees which give government research and development funds to projects that improve the work environment. This allows German unions to lobby for inclusion of health and safety features into new technology at the developmental stage.

Further, German unions are seeking a requirement that they be consulted before employers and equipment suppliers are given government money to experiment with production systems, such as computerized machine tools and industrial robots.

When a local union in Europe uses its rights to respond to technological change, the results can provide quite a contrast to comparable situations in the United States. For example, metal workers at an aircraft parts plant in Kongsberg, Norway, have had far more success in coping with the introduction of computer-based machine tools than have workers at a similar plant in Lynn, Massachusetts.

At Kongsberg, the trained union technology committee received complete information before the computerized machine tools were installed. On the basis of this information, the committee insisted that machine operators already on the job be trained to do the computer programming and repairs. As a result, the machinists' skills were broadened rather than narrowed by the technological change.

In contrast, at Lynn, the equipment was installed without consultation with the union. Now supervisors or nonunion programmers handle the computer work, thereby reducing many skilled machinists to "machine tenders" or "button pushers" with less interesting work and lower pay. Job losses for union members are possible, and any future job action by the union will be less effective. ☐

Cost-of-living indexes for Americans living abroad

The U.S. Department of State has computed new indexes of living costs for selected foreign cities. These indexes compare the costs (in dollars) of representative consumer goods and services (excluding housing and education) purchased at foreign posts with the costs of comparable goods and services in Washington, D.C.

In most of the foreign cities, living costs for Americans are higher than in Washington, D.C. However, in the last 2 years, relative costs have declined in many cities, as the appreciation of the U.S. dollar exchange rate offset, in part, the higher prices abroad.

For example, although prices in Switzerland increased at the same rate as in the United States, living costs were down 22 percent in Geneva—from 176 to 137—according to the May 1981 index, because 21 percent of the higher Swiss prices was offset by the appreciation of the U.S. dollar. Similarly, living costs for Americans were down 8 percent in Tokyo—from 155 to 142—according to the February 1982 index. Japanese prices rose 3 percent more than U.S. prices over the previous year, but appreciation of the dollar offset 10 percent of the higher Japanese prices.

The new index for Rome, however, shows living costs down by only 4 percent, even though the U.S. dollar exchange rate appreciated about 25 percent, because consumer prices in Rome rose 20 percent more than prices in Washington, D.C. In some countries, recent price increases have been greater than the appreciation of the dollar. For example, the new (January 1982) index for Mexico City showed U.S. dollar costs for Americans up 6 percent over the previous year because, while the dollar appreciated 12 percent versus the peso, Mexican prices rose 19 percent more than U.S. prices. (In February, the peso was devalued, and costs for Americans have sharply declined.)

It is advisable to check the prevailing exchange rates whenever using the indexes of living costs abroad because the rates are subject to sudden shifts, and different rates would substantially affect living costs in dollars.

The indexes of living costs abroad are computed in order to establish allowances for American government employees assigned to foreign posts where the cost of living is significantly higher than in Washington, D.C. In addition, indexes are computed for American private employees. (The indexes shown in table 1 are those computed for private Americans.) The indexes and post allowances cover most living costs, except housing and education which are covered by separate allowances.

The indexes of living costs abroad and quarters (housing) allowances for selected foreign cities are published quarterly by the Bureau of Labor Statistics. They are now available by subscription, or single copy, from the Superintendent of Documents. The new subscription series include indexes for more than 160 cities, housing allowances for about 75 cities, and hardship differentials for all important hardship posts.

U.S. Department of State Indexes of Living Costs Abroad, Quarters Allowances, and Hardship Differentials can be ordered from the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Price for an annual subscription (four quarterly issues) is $6.50 domestic, $8.15 foreign; individual copies, $1.75 domestic, $2.20 foreign. A description of the statistics and overseas allowances system, *U.S. Department of State Indexes of Living Costs Abroad and Quarters Allowances: A Technical Description* (Report 568), is available from the Bureau of Labor Statistics. ☐

Table 1. Indexes of living costs abroad, excluding housing and education, July 1982

[Washington, D.C. =100]

Country and city	Survey date	Monetary unit	Rate of exchange per U.S. Dollar	Local index

Special Labor Force Reports—Summaries

Labor force patterns of students, graduates, and dropouts, 1981

ANNE McDOUGALL YOUNG

After having increased for nearly two decades, the labor force participation rate for students age 16 to 24 began to slip in 1978, starting a downward trend that was still evident in the early 1980's. Most of the decline has occurred among teenagers, especially those 16 and 17.

For out-of-school youth 16 to 24, the labor force pattern over the past two decades has mirrored the trend among adults 25 and over. Rates for young men drifted down, while those for young women advanced strongly. (See table 1.)

Detailed information on the work activity of school age youth is obtained from a special survey conducted each October. This report summarizes data that have recently become available from the 1981 survey.[1]

School and work

About 46 percent of the students 16 to 24 were in the work force in October 1981, down from nearly 49 percent in 1978. This decline may be related to a number of factors, including the possibility of greater competition with women over 24 for jobs, especially for part-time jobs, and perhaps some discouragement with employment prospects as economic growth has slowed.

Some analysts have suggested that the labor force activity of school age youth has been affected by the increased labor force participation of women.[2] For example, James Grant and Daniel Hammermesh have concluded that "competition from adult women has very likely had a negative impact on the labor market for youths."[3] During the expansionary era of the 1960's and early 1970's, student labor force rates rose along with those for women. However, in the late 1970's and early 1980's, the competition for jobs has intensified, and students were often looking for the same jobs that were also sought by older women.

The decreases in labor force participation rates of students have not changed the historical pattern by race—the highest rates being for whites, followed by Hispanics, and the lowest for blacks. However, while the participation rate for white students remained relatively unchanged from 1980 to 1981, the rate for black students dropped to the 1975 recession level. The trend for male Hispanic students has been similar to that for blacks, while the rates for Hispanic women have been too volatile to detect a trend.

Labor force participation rates for young women no longer in school have been an exception to the trend among youth, rising by 13 percentage points since 1970. In part, this rise reflects the growing proportion of young women who have completed high school, and the much higher labor force rates of graduates, compared with dropouts. Probably more important was the increase in proportion of out-of-school 16-to-24-year-old women who are not yet married—from a third in 1970 to a half in 1981.[4] Their labor force rate was 82 percent, compared with 64 percent for their ever-married (that

is, married, divorced, separated, or widowed) counterparts. Labor force participation of women no longer in school rose regardless of race or ethnicity.

In general, there has been a relatively steady decline in the labor force participation rates of black male youth no longer in school. Whereas their labor force rate equaled that of their white counterparts in 1960, by 1981 there was a 10-percentage point difference. Research on the declining participation rates has produced contradictory results regarding the influence of the suburbanization of many youth jobs, the significance of the minimum wage, and the importance of personal characteristics which youth bring to the job.[5]

Some reports have suggested that because of various forms of discouragement—such as high unemployment rates among peers, older friends, and neighbors; the limited range of jobs available; and the perception of lingering discrimination—some youth may have decided that the job search was not worth continuing. Paul Osterman's study of labor force activity among inner-city youth, based on decennial census data, showed that there was "a considerably more powerful discourage-

ment effect" for black youth in 1970 than in 1960 and reasoned that "this doubtlessly explains the adverse participation trends over the decade."[6] A recent study suggests that some black out-of-school teenagers whose families were on welfare may be inhibited from working because their family allowance would be reduced by the amount of their earnings.[7]

Unemployment rates

Unemployment rates for youth in and out of school have fluctuated considerably since 1970. From 13.2 percent for the enrolled and 10.9 percent for not enrolled youth in 1970, they reached 15.0 and 14.9 percent in 1975, dropped to 12.5 and 10.0 percent in 1978, and climbed back to 14.4 and 15.0 percent in October 1981. These changes reflected not only the recessions in 1975 and 1981, but also continuing problems with finding part-time jobs to fit the schedules of students, and full-time jobs to match the varying skills and educational attainment of out-of-school youth. While it is to be expected that youth unemployment rates would be particularly vulnerable to cyclical changes, the rates for youth have been much higher during the past decade than in the 1960's.

Within the enrolled group, the unemployment rate for male students was relatively unchanged over the year, whereas the rate had increased sharply for women. (See table 2.) Most of the rise occurred among female high school students but teenage women in college were also affected. Only the 20-to-24 age group was untouched by increased joblessness. The unemployment rate for black teenage students rose to 45.4 percent over the year, nearly three times that for whites. Again, most of the increase was among women in high school. Hispanic students' jobless rate remained stable.

Among youth no longer in school, unemployment rates ranged from 5.3 percent for college graduates to 26.9 percent for high school dropouts. As was the case for students, the burden of increased unemployment over the year was limited to women. Their overall unemployment rate rose almost 2 percentage points while the rate for men held steady. Only women who had graduated from college showed no change in their unemployment rate, which continued to be somewhat lower than the rate for male college graduates in the age group. Out-of-school black youth have historically had very high unemployment rates; in October 1981, about a third of those in the labor force were looking for work. The unemployment rate for Hispanic youth (15.4 percent) differed little from that for whites.

Recent graduates and dropouts

A record 1.6 million youth who graduated from high school in 1981 were attending college in October 1981. (See table 3.) Some 54 percent of all recent graduates were enrolled, compared with 49 percent a year earlier. A similar surge in college enrollment occurred during the 1974–75 recession when many youth chose school as an alternative to unemployment or a less desirable job. The labor force participation rate of new college students was 44 percent, substantially higher than in the early 1970's, reflecting, in part, the increase in work-study programs associated with student aid.[8]

Most recent high school graduates who did not go on to college were in the labor force in October. At 84 percent, their labor force participation rate was also higher than in 1970, mostly because of an increase in the rate for women. The unemployment rate for recent graduates not in college—21.4 percent—was substantially

higher than a year earlier. It was also higher than the rate for all youth in the age group with 4 years of high school only (13.8 percent).

College students at work

Labor force participation of students is constrained by geography, classroom schedules, and transportation facilities, as well as general conditions in the economy. With opportunities for employment generally limited to the vicinity of the college, the growth of 2-year colleges in metropolitan areas has allowed many persons to further their education while holding down a job. The particular importance of employment for part-time students is shown in table 4. Almost 9 of 10 such students were in the labor force in October 1981.

The close connection between part-time schooling and labor force activity is further illustrated by the low unemployment rates for such students, regardless of race or ethnic origin. The decision to attend college part time, and the means to pay for it, appear to be directly linked to the desire for advancement by youth already employed. The unemployment rates for part-time students were about the same for whites and blacks and were consistently much lower than the rates for full-time students.

Hispanic youth, some of them relatively new to the United States,[9] have made extensive use of low cost, 2-year community colleges—almost 50 percent of all Hispanic college students were enrolled in such colleges in 1981, compared with 28 percent of the white, and 29 percent of the black students. More than half of the Hispanic students were working while attending school.

Black students were much less likely than either white or Hispanic students to combine work and college. The lower labor force participation rates of black college students have persisted despite their much lower family income. A third of their families had incomes of less than $15,000 compared with a tenth of the white families and a fourth of the Hispanic families with students in college in 1981. Whereas many jobs in retail sales, food, and other service industries have moved to suburban malls, the majority of black students live in central cities.[10] Lack of convenient transportation may limit their access to jobs located on the periphery of the city. The substantial number of students attending the many black colleges located in rural areas also face limited employment opportunities. ☐

——FOOTNOTES——

[1] This report is based primarily on supplementary questions in the October 1981 Current Population Survey, conducted and tabulated for the Bureau of Labor Statistics by the Bureau of the Census. Most data relate to persons 16 to 24 years of age in the civilian noninstitutional population in the week ending Oct. 17, 1981.

Sampling variability may be relatively large in cases where the numbers are small. Small estimates, or small differences between estimates, should be interpreted with caution. Major Agreements Expiring Next Month

This list of collective bargaining agreements expiring in October is based on contracts on file in the Bureau's Office of Wages and Industrial Relations. The list includes agreements covering 1,000 workers or more.

Employer and location	Industry	Labor organization[1]	Number of workers
American Enka Corp. (Lowland, Tenn.)	Chemicals	United Textile Workers	2,400
Bayly Corp. (Interstate)	Apparel	Clothing and Textile Workers	1,200
Chain and Independent Food Stores (New Mexico)[2]	Retail trade	Food and Commercial Workers	2,300
Colonial Stores, Inc., Raleigh Division (North Carolina)	Retail trade	Food and Commercial Workers	1,400
Consolidated Gas Supply Corp. (Interstate)	Utilities	Service Employees	1,750
Cotton Garment and Outerwear Agreement (Philadelphia, Pa.)[2]	Apparel	Clothing and Textile Workers	1,550
Dayton Power and Light Co. (Ohio)	Utilities	Utility Workers	2,600
General Motors Corp. (Interstate)	Transportation equipment	Plant Guard Workers (Ind.)	2,550
General Telephone Company of Illinois, Service, Construction and Supply Departments (Illinois)	Communication	Electrical Workers (IBEW)	1,750
GTE Sylvania, Inc. (Seneca Falls, N.Y.)	Electrical products	Steelworkers	1,000
Hesston Corp. (Hesston, Kans.)	Machinery	Hesston Corporation Workers Association	1,450
Hotel Association of Ohio (Ohio)	Hotels	Hotel Employees and Restaurant Employees	1,600
Jewel Companies, Inc., Eisner Food Stores Division (Chicago, Ill.)	Retail trade	Retail Workers	1,400
Mack Trucks, Inc., Master Shop Agreement (Interstate)	Transportation equipment	Auto Workers	6,250
Massey-Ferguson, Inc., Master Agreement (Interstate)	Machinery	Auto Workers	1,500
Pittsburgh Buildings Association (Pennsylvania)	Services	Service Employees	1,200
Retail Butchers Fish and Poultry Agreement (California)[2]	Retail trade	Food and Commercial Workers	3,500
Retail Meat Markets and Frozen Food Locker Plants (California)[2]	Retail trade	Food and Commercial Workers	1,500
Rubbermaid, Inc. (Wooster, Ohio)	Rubber	Rubber Workers	1,300
Simmons Co. (Interstate)	Furniture	Upholsterers	2,100
TRW, Inc. (Ohio)	Transportation equipment	Aircraft Workers Alliance, Inc. (Ind.)	4,000
Wisconsin Public Service Corp. (Wisconsin)	Utilities	Operating Engineers	1,000

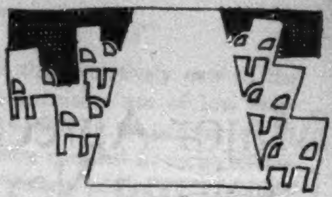
Developments in Industrial Relations



Job security focus of GE contract

After 2 months of negotiations, the General Electric Co. and 13 unions representing 100,000 workers settled on 3-year contracts that featured improved job security provisions. The breakthrough in the negotiations occurred when the two unions that bargain with GE on a "national" basis—the International Union of Electrical Workers (representing 65,000 workers) and the United Electrical, Radio, and Machine Workers (13,000 workers)—settled. Afterwards, the other member unions of the Coordinated Bargaining Committee settled on the same terms. Six of the unions had initiated the committee in 1965 to strengthen their bargaining position with GE and with Westinghouse Electric Corp. (See "Collective Bargaining in the Electrical Machinery, Equipment, and Supplies Industry," *Current Wage Developments*, March 1982, pp. 42–44.)

One of the job security provisions specifies that workers shifted to lower-rated jobs because of the transfer of work or the introduction of robots or automated manufacturing machines will be guaranteed their former pay rate for 26 weeks. Following are other job-security provisions which are separate from the existing Income Extension Aid Program that applies only to laid-off workers:

- GE agreed to give a 6-month notice of plant closings or transfers of work and a 60-day notice before the use of robots or automated manufacturing machines.
- The lump-sum severance payment for 15-year workers affected by plant closings was increased from 1 week to 2 weeks of pay for each year of service. For other employees with at least 2 years of service, the payment was set at 1.5 weeks of pay for each year, with a minimum of 4 weeks of pay.
- A liberalized table of age and service requirements that made more terminated employees eligible for monthly income instead of severance pay until they are re-employed or reach optional retirement age. Under the revised table, eligibility ranges from employees age 50 with 25 years of service to those who are age 55 with 10 years of service. The benefit equals 2 percent of monthly pay multiplied by years of service, up to 50 percent of current pay.
- Employees at least 50 years of age with a minimum of 25 years of service who are affected by plant closings will not have their pensions actuarily reduced. Instead, their benefits will be calculated as if they are age 60. They will also receive a supplement of up to $175 a month until age 62.
- Employees with at least 7 years of service who are affected by plant closings will have a vested pension right.
- Displaced workers will receive job placement assistance and up to $1,800 for education and retraining.
- Employees who are at least age 50 with at least 25 years of service who are affected by plant closings will continue to be covered by company-financed medical and life insurance until they are 65 or find another job. Dependents also will be eligible for insurance continuation, if they continue to make a contribution toward the premium cost.

The accord called for a June 28, 1982, general pay increase of 7 percent plus a special "decompression" pay adjustment of 2 cents an hour for employees earning $8.35 to $8.49 an hour, 4 cents for those earning $8.50 to $8.64, 6 cents for those earning $8.65 to $8.79, and so forth. The parties indicated that the special pay adjustment for higher skilled workers and the percentage general increase (rather than a flat cents per hour increase of equal cost) were provided to relieve a compression of the pay rate structure.

The workers also will receive 3-percent specified pay increases in June of 1983 and 1984. The provision for automatic semiannual cost-of-living pay adjustments was modified to provide for pay increases of 1 cent an hour for each 0.175-percent rise in the Consumer Price Index for Urban Wage Earners and Clerical Workers, beginning June 27, 1983. The first adjustment during

---

"Developments in Industrial Relations" is prepared by George Ruben of the Division of Developments in Labor-Management Relations, Bureau of Labor Statistics, and is largely based on information from secondary sources.

the agreement term (on December 27, 1982) will be calculated at the previous rate of 1 cent for each 0.2-percent movement in the index.

The parties said that specified and cost-of-living pay adjustments will average $2.10 an hour, or 23.3 percent, over the agreement term, based on an assumed price index rise of 6 percent a year.

There were a number of improvements in the pension plan. Under the formula that applies to most retiring workers, benefit rates were raised to $12–$17.50 a month, varying according to pre-retirement average annual earnings, for each year of service, effective July 1, 1982, and to $14–$19.50 on January 1, 1984. The previous range was from $10 to $15. Comparable changes also were made in the alternate pension formula. Beginning in 1983, the employee contribution toward pensions will be 3 percent of that portion of annual earnings in excess of $12,000 (formerly $9,000).

Other improvements included 5 weeks of vacation after 20 years of service, instead of 25 (maximum time off remained at 6 weeks after 30 years); $500,000 instead of $350,000 catastrophic medical coverage; $30,000 instead of $20,000 minimum life insurance; and starting in 1983, $225 instead of $200 maximum sickness and accident benefits for disabilities.

Negotiations were continuing at Westinghouse, where contracts in recent years have usually been patterned after GE agreements. The Westinghouse negotiations involve more than 50,000 workers.

Teamsters, United Parcel Service settle

Nearly 85,000 Teamsters members were covered by an agreement with United Parcel Service (UPS) that did not provide for any specified wage increases over its 37-month term, ending on June 1, 1985. This was similar to the union's settlement with the general trucking industry. (See *Monthly Labor Review*, April 1982, p. 64.)

The UPS settlement followed the trucking agreement in changing from semiannual to annual cost-of-living adjustments calculated at 1 cent an hour for each 0.3-point movement in the Consumer Price Index for Urban Wage Earners and Clerical Workers (1967=100). Both settlements called for diverting part or all of the cost-of-living adjustments to meet the cost of maintaining existing levels of pension and insurance benefits. However, there was no diversion from the 72-cent May 1982 adjustment for UPS workers, in contrast to the general trucking workers, whose April adjustment was reduced by 25 cents an hour.

A paid holiday also was added, bringing the total to 10 to 15 days a year, depending on the region. This was the second agreement negotiated on a national basis; previously, agreements were negotiated on a regional basis.

One major provision in the UPS agreement stipulates that part-time workers hired in the future be paid lower rates—$8 an hour for unskilled workers who load and unload trucks, and $9 for skilled workers who sort parcels. All of the company's drivers are full time.

These reduced rates, and the lack of specified wage increases, drew strong criticism from Teamsters for Democratic Union, a dissident group that has been contesting the union's leadership in recent years. The organization claimed that the pay freeze was not warranted because UPS was operating at a profit, unlike many freight companies, and that the special pay rates would induce UPS to increase its percentage of part-time workers. Despite this criticism, the vote tally was 33,072 to 29,788 in favor of the contract, not close to the two-thirds negative vote needed for rejection.

Ship officers and engineers give back pay increase

More than 7,000 licensed marine ship's officers agreed to roll back a June pay increase of 7.5 percent in response to a request from the Reagan Administration. Jesse Calhoun, president of the Marine Engineers Beneficial Association, said members of his union accepted the cut to aid the Administration's effort "to develop an affirmative and much needed maritime program." Two unions of unlicensed seamen, the Seafarers' International Union and the National Maritime Union, rejected the request, saying that their labor contracts "are by no means out of line with the economic realities of the maritime industry, or the Nation as a whole."

Utility contract features lifetime job security

More than 3,500 employees of the Potomac Electric Power Co. in Maryland, Virginia, West Virginia, and the District of Columbia were covered by a settlement negotiated by the International Brotherhood of Electrical Workers that called for pay increases of 9, 8, and 8 percent in June of 1982, 1983, and 1984. The 3-year accord also provides "lifetime job and pay security" to employees with 12½ years of seniority. According to the union, eligible employees "cannot be furloughed or reduced in pay due to lack of work, plant closings, reorganizations, automation, etc." In return, the workers agreed to changes in "duties and responsibilities" provisions to improve operating efficiency.

A company source said the changes in duties and responsibilities provisions permit PEPCO to adapt to changing conditions and operations by making changes in job content without union approval. This provision is subject to review after a 2-year trial period.

Other contract terms included—

- A 3.3-percent special pay increase to 1,500 workers whose job content had been increased in the past without a commensurate pay increase. This special adjustment was in exchange for ending all of the grievances employees had filed because of the job content changes.

- A new absence and sick leave program designed to reward workers with good attendance and penalize those with poor records.
- Establishment of a company-financed dental care plan.
- Elimination of the provision for an automatic cost-of-living pay adjustment. (The adjustment under the prior contract was 20 cents, effective March 1, 1982.)

Six-month raises for supermarket workers

In the New York City area, 13,000 workers were covered by a settlement between United Food and Commercial Workers Local 1500 and 10 supermarket chains. The 3-year contract provided for full-time employees to receive a wage increase of $90 a week, consisting of a $30 immediate increase, followed by $20, $10, $20, and $10 increases at 6-month intervals, beginning in June 1983. Increases for part-time workers were 50, 30, 15, 30, and 15 cents an hour on the corresponding dates.

The pension rate for full-time workers was increased to $17 a month for each year of credited service (from $11) effective September 1, 1982, and to $20 in September 1984. It will be financed by a two-step increase in the employer's funding obligation to $71.55 a month, from $45. Employer funding of pensions for part-time workers also was raised and they will continue receiving benefits at half the rate that applies to full-time workers.

The employers' financing of welfare benefits for full-time employees was increased by $20 a month (to $108) over the term to permit a number of improvements, including $250,000 major medical coverage (formerly $100,000); $20,000 (instead of $10,000) life and accidental death and dismemberment insurance; a prescription drug coverage plan; and increasing dental and vision care coverage. There also were improvements in welfare benefits for part-time workers.

Other provisions included a fifth week of vacation for full-time employees with 25 years of service and a prohibition of mandatory lie detector testing.

Warehouse workers get new contract

In Northern California, the Teamsters and International Longshoremen's and Warehousemen's unions settled jointly with two warehouse associations on 3-year contracts for 5,000 workers. The settlement with the Industrial Employers and Distributors Association and the San Francisco Employers Council also had a wider impact, as the two unions then won similar terms for 15,000 other warehouse workers.

Wages will increase by 32 cents an hour in December 1982 and 24 cents in June of 1983 and 1984, bringing the contract minimum wage rate to $11.59 an hour. The cost-of-living clause, which was not changed, provides for pay adjustments in June of 1983 and 1984 each equal to 1 cent an hour for each 0.3-point rise in the Consumer Price Index for All Urban Consumers (1967=100) in excess of 7.2 index points during the preceding 12 months, with no credit toward the adjustments for any rise in excess of 11 percent. The parties estimated that the resulting adjustments will total 89 cents, assuming rise of 7 percent a year.

Both contracts provided for a 37-cent-an-hour increase in employer financing of benefit improvements, which were not identical for both unions.

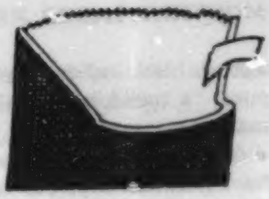
Employer need not remain neutral, NLRB rules

The National Labor Relations Board reversed a policy initiated in 1945 by holding that employers do not have to stay strictly neutral when unions compete for the right to represent their employees. The new policy was manifested in rulings involving a subsidiary of RCA Corp. located in Puerto Rico and the Bruckner Nursing Home, located in New York.

In the RCA case, the board held that the employer must continue to recognize and negotiate with an incumbent union when another union asks the board to conduct a representation election. The board said this approach should further "stability in industrial relations" while ensuring "employee free choice."

In the nursing home case, the board held that a non-union employer need not remain neutral until an election petition is filed by one of the competing unions. Instead, the employer voluntarily may recognize the union that signs up an "uncoerced, unassisted" majority of workers in a bargaining unit. □

Book Reviews



The long struggle of working women

Out to Work: A History of Wage-Earning Women in the United States. By Alice Kessler-Harris. New York, Oxford University Press, 1982. 400 pp. $19.95.

The idea of writing a history of wage-earning women in the United States was an excellent one and Alice Kessler-Harris provides much information, particularly about the period before the Second World War. It is also refreshing to read a work on the role of women in the economy written from the perspective of a historian rather than a sociologist or economist. The book is clearly well researched and brings many unfamiliar sources to print.

In some sense, however, it is these strengths of the book that are also its weaknesses. The historian's approach, focusing on letters and other primary sources, seems to one accustomed to social science research to be generalizing from anecdotes rather than from data. Moreover, misunderstandings of the nature of change often occur from the use of anecdotal evidence. For example, today we are familiar with articles that include interviews with female plumbers, auto mechanics, and truckdrivers. While it is true that some women have moved into traditionally male occupations, it would be wrong to conclude that such occupational changes have become commonplace. Thus, it is natural to wonder whether the letters of Ann Appleton to her sister Sarah in 1847, or those of Lucy Davis, or Melinda Edwards or the others, are truly representative. The relevance of the historical approach could have been supported by a greater use of the available statistics to set the stage.

The work could also have benefited from better integration with developments in American economic history. The role of all workers, and especially women, has been influenced by changes in the industrial structure of the Nation, the types of goods and services that were *demanded, and the organizational structure* that was established to supply the demand.

The book is at its best covering the world of work among women with little education. Manual workers, those in sales and clerical jobs, and domestic workers all play a major role in the book, but professional women are barely mentioned, although women have been working in nursing, teaching, and other "helping professions" for many years.

The coverage of the period since the Second World War is very sparse; actually, it might have been better for it to have been omitted altogether. So much has been written about this period in other books and journals that the coverage in *Out To Work* seems superficial.

No book can be expected to provide complete coverage, however; and despite its limitations the work fills a serious gap in our knowledge about working women in the 18th and 19th centuries. It reminds us most dramatically that the road to the present was not a straight or level one and that working women in the past suffered problems that are hard to even imagine today.

A few statistics can help put the transformation in perspective. Prior to 1900, less than one-sixth of all working women were married; today more than half are. In 1900, more than half of women who worked held blue-collar or private household jobs; today, only one-sixth are engaged in those types of employment. The proportion of all women in the paid work force went from one-fifth in 1900, to one-fourth in 1940, to one-third in 1960 and one-half in 1980. At the same time, the typical job held by a woman was transformed from one requiring long hours of physically tiring work to one that was likely to be sedentary, in clean and safe surroundings, and otherwise more desirable.

Race, class, and income inequality

Racial Inequality. By Michael Reich. Princeton, N.J., Princeton University Press, 1981. 345 pp. $22.50.

This book may prove tough going for readers who do not share the author's political perspective, class conflict. Michael Reich believes that racial discrimination against blacks affects white workers as well and proposes "a broad interracial [working] class alliance" to redistribute economic and political power.

Others may view the combination of a Marxian-tinted framework and rigorous econometric analysis as novel. But it is quite possible to both find Professor Reich's review of persistent income inequality by race well developed, while rejecting his singular interpretation and solutions.

Reich's analysis examines the embedded effects of a socioeconomic class structure rather than standard discrimination theory to explain income differences by race. Because neoclassical theory does not envision persisting differences, especially in the long run, the book makes a valuable contribution in its clear exposition of those discrepancies.

In his focus on economic inequality rather than employment discrimination, the author provides an explanatory framework for how such differences can persist. This focus almost ignores gains by individuals, especially by race, however, leaving Reich with results not necessarily related to his interpretation.

Employment gains by blacks over the past decade attributable to voluntary or judicially directed compliance with the Civil Rights Act, or to enhanced access to job-qualifying education and training, play no role in Reich's schema, for example. A wage-subsidization-by-race effect of the magnitude required to demonstrate such a phenomenon is not possible where industrial wages are set by job level and seniority, not worker characteristics.

To the extent that preferable job assignments, carrying higher wage levels, are improperly distributed by race in a few instances, legal remedies exist for redress. Reich's results, drawn from 1960 and 1970 census data, unfortunately fail to reflect changes over the past decade affecting the conclusions that may be drawn from them.

The underlying hypothesis rests on several findings. In particular, Reich found that owners of capital, and whites in the upper decile, are concentrated in those areas where racial income inequality is most extreme and the presence of a redistributive effect of this inequality away from white as well as black workers.

But because the geographic redistribution of American wealth into energy-related capital strongly overlaps those regions where income is less evenly distributed to begin with, a nexus tying race and class to earnings ultimately fails to illuminate the question. If the author wants to assert that discrimination against blacks harms all but wealthy whites (what about wealthy blacks?), more clearly developed proof is required. It is not provided.

Reich's critique of the major neoclassical models, and why they lack explanatory value as to racial discrimination is crisply written, building on his previous work. The author's own theory would have to show more persuasively how the owners of capital consciously scheme to deprive wage earners of anything on the basis of race beyond the compensation package, particularly as to terms and conditions of employment.

As Reich said of Gary Becker's pioneering study on the economics of discrimination, "it deserves much credit for bringing the subject into the mainstream of economic analysis." Similarly, this study deserves credit for its effective summary and review of the extant literature, and the tenuous relevance of much of accepted theory to a persisting long-term problem.

But a cogent critique of earlier theory does not imbue the author's own work with validity. Reich pinpoints the difference wherein neoclassical theory treats labor strictly as a commodity rather than a combined commodity and dynamic noncommodity, capable of interacting with the other factors of production. This does not explain how the combination of market processes and capitalist-worker conflict will result in a lessening of inequality, however.

Furthermore, Reich identifies managers and professionals as an intermediate group "between" workers and capitalists. Yet the presence of this stratum suggests that the working class solidarity required for any major shift in economic power is completely absent.

The dichotomy between the author's analysis and conclusion is further illustrated by his statement: "The class conflict theory accords with econometric evidence indicating that most white workers are hurt by racism. These results strengthen the advantages of the class conflict theory over the neoclassical theory." While that view is open to debate, it is nonetheless a *non sequitur* to the material that precedes it pertaining to the distinction among and between the factors of production.

The lack of movement toward Reich's solution, an interracial working class coalition, is clear to all, including the author. This is explained in part by antiblack attitudes within organized labor that have resulted in the continued disadvantage of white workers, in Reich's view.

An equally plausible perspective may be mentioned. That is, the lack of union power across much of the Nation, especially in the Southern half, combined with the diminished lack of economic vitality and reduced labor demand of recent years, has affected the income of workers far more than the factors cited by Reich.

Because most capitalists and skilled workers are white, the effects of a somewhat noncompetitive market structure tend to skew the Nation's income distribution on several dimensions including race. But many, if not most, white workers (along with most black workers) fail to enjoy the incomes they might obtain under a more balanced economic structure.

The book has its strong points, especially chapter 4. It should most certainly be welcomed by readers seeking broader exposure to non-mainstream economic thought.

But American workers have not transformed trade unionism into a radical political institution or a European-type structure. Nor is a multiracial coalition likely to emerge to redistribute earned income by race and class simultaneously.

This leaves Reich committed, *a priori*, to a conclusion at odds with how workers of both races behave, and the distribution of their incomes as a result. The dynamic durability of industrial and social institutions, particularly those outside the workplace that affect occupational qualifications and choice patterns, must be more thoroughly investigated with 1980 census data before a clearer and more realistic explanation can emerge.

A new role for corporations

Corporate Control, Corporate Power. By Edward S. Herman. New York, The Twentieth Century Fund, Inc., 1981. 432 pp. $18.95, Cambridge University Press, New York.

Fifty years have passed since the shift of control from owners to managers in the increasingly dominant major corporations was analyzed in the classic work, *The Modern Corporation and Private Property*, by A. A. Berle, Jr. and Gardner Means. With support from the Twentieth Century Fund, Edward S. Herman, Professor of Finance at the University of Pennsylvania's Wharton School, has reexamined the earlier findings based on contemporary corporate developments.

Managerial control of the corporation is Herman's starting point. For this, he has painstakingly combined thorough examination of the accumulated voluminous literature and analytical studies of corporations in recent years with his own carefully developed conceptual and statistical analysis. The initiating purpose of the study is achieved through the treatment of the operational elements for internal corporate control; the changing role of ownership among individuals, families, and financial institutions; and external influences on corporate control. As executed, the study is equally a treatment of the role of the corporation in today's American society. The context of the study derives from Herman's long interest in the centralizing role of the corporations, and in the possibilities and limits of corporate interaction with reform and social change. The breadth of his treatment is expressed in his perception which "stresses the continued primacy of corporate initiatives in economic change, the great powers of corporate resistance to profitable growth and the resultant strong tendencies toward political immobility."

Regarding the managerial locus of corporate control reported by Berle and Means, Herman demonstrates the accentuation of that corporate characteristic. While reformulating some of the Berle and Means classifications, Herman finds that the substantial decline in ownership control of corporations had already occurred by 1900, with the level changing little by 1929. There was, however, a contrasting sharp drop between 1929 and 1975. In 1929, owner-controlled companies accounted for 42 percent of the number and 28 percent of the assets of the 200 largest companies; in 1975, owner-controlled companies numbered 16 percent, with 13 percent of the assets of the 200 largest. There has also been a decline in controls exercised by banking and speculative interests.

This reinforcement and intensification of control by managers with relatively little stock ownership in their companies has not meant that these are neutral technocrats, as Berle and Means postulated, who are less concerned with profits than in owner or entrepreneurial-run companies. Herman finds that the evidence demonstrates that such managerial-controlled companies do not significantly differ in objectives from owner-controlled companies. Management confronted with the constraints induced by the concerns of owners and creditors and the workings of internal group decision-making is just as concerned with achieving profitable growth as are the owners. Management is in a strategic position to function with a substantial degree of autonomy, although internal and external constraints affect its extent. These constraints include the relative position of unions in bargaining, governmental tax and regulatory requirements, community pressures, relations with other firms, and other corporate interests by the board of directors.

Viewing the role of corporations in the American economy, Herman points to their increasingly dominant role, already apparent in 1900. These major firms are interconnected through a loose network of joint ventures, interlocking directorates, government advisory bodies, and a variety of social, political, and trade groups. At the same time, there are new dissociative factors, with price competition replaced by product competition resulting from the high rate of technological change. Furthermore, the internationalization of business since 1945, while making markets more open and global, has enhanced the power of the multinational corporation in individual countries and increased its autonomy. Flexibility of movement increases the corporation's bargaining position with unions. The effect on government is dualistic and paradoxical—at one and the same time, the role of government is enhanced, with appeals for assistance from both expanding multinationals and threatened domestic interests; yet the government role is weakened by the conflicts between domestic interests and international pressures as well as by events determined by private initiatives.

Such transcendent influences have engendered concerns with corporate reforms which include assertions of the need for corporate perspectives to include wider social responsibilities. Herman points to the long and widely held corporate leadership views that social responsibility was met by serving the community through the corporation's regular productive activities, and not through charitable activities. Herman suggests the need for broader societal approaches, than those usually suggested, to raise corporate perspectives beyond short-term concerns with profitable growth, and long-term concerns with such limited matters as sources of raw materials and market positioning. Broadening representation on corporate boards of directors, either through outside directors or worker participation, is not viewed as assuring significant changes in the horizons of corporate objectives.

Rather, Herman appeals for awareness of the urgency for meeting the broad evolving needs of domestic and international society in which corporations play a major role. He calls attention to alternative possibilities, leaning towards what he refers to as the French, Japanese, and Swedish "Models of Guided Capitalism." Adaptation of elements of these economies in the American ambience would only involve modest external shocks for the present order, while permitting "greater and more explicit partnership arrangements between government and big business to deal with both internal and external needs." He stresses that these models function within a democratic framework, rather than the authoritarian approaches taken in some third world countries. The warning is set forth that "in a revised 'stages of growth' model, instead of third world political economies becoming like us, under conditions of slower growth, severe factionalism, and major systemic shock, we may become more like them." Herman has contributed importantly to the literature of political economy by relating his technical findings to the broader fluctuative social, economic, and political climate currently buffeting governments, corporations, unions, and the public at large.

35. Work stoppages involving 1,000 workers or more, 1947 to date 91

NOTE

Tables 10 and 13 have been deleted, and the succeeding tables renumbered.

NOTES ON CURRENT LABOR STATISTICS

This section of the *Review* presents the principal statistical series collected and calculated by the Bureau of Labor Statistics. A brief introduction to each group of tables provides definitions, notes on the data, sources, and other material usually found in footnotes.

Readers who need additional information are invited to consult the BLS regional offices listed on the inside front cover of this issue of the *Review*. Some general notes applicable to several series are given below.

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might otherwise mask short-term movements of the statistical series. Tables containing these data are identified as "seasonally adjusted." Seasonal effects are estimated on the basis of past experience. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years.

Seasonally adjusted labor force data in tables 2–7 were revised in the March 1982 issue of the *Review* to reflect experience through 1981. The original estimates also were revised to 1970 to reflect 1980 census population controls.

Beginning in January 1980, the BLS introduced two major modifications in the seasonal adjustment methodology for labor force data. First, the data are being seasonally adjusted with a new procedure called X-11/ARIMA, which was developed at Statistics Canada as an extension of the standard X-11 method. A detailed description of the procedure appears in *The X-11 ARIMA Seasonal Adjustment Method* by Estela Bee Dagum (Statistics Canada Catalogue No. 12-564E, February 1980). The second change is that seasonal factors are now being calculated for use during the first 6 months of the year, rather than for the entire year, and then are calculated at mid-year for the July-December period. Revisions of historical data continue to be made only at the end of each calendar year.

Annual revision of the seasonally adjusted payroll data shown in tables 10, 12, and 14 were made in August 1981 using the X-11 ARIMA seasonal adjustment methodology. New seasonal factors for productivity data in tables 28 and 29 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month to month and from quarter to quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average All Items CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100. For example, given a current hourly wage rate of $3 and a current price index number of 150, where 1967 = 100, the hourly rate expressed in 1967 dollars is $2 ($3/150 × 100 = $2). The resulting values are described as "real," "constant," or "1967" dollars.

Availability of information. Data that supplement the tables in this section are published by the Bureau of Labor Statistics in a variety of sources. Press releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule given below. The *BLS Handbook of Labor Statistics*, Bulletin 2070, provides more detailed data and greater historical coverage for most of the statistical series presented in the *Monthly Labor Review*. More information from the household and establishment surveys is provided in *Employment and Earnings*, a monthly publication of the Bureau. Historically, comparable information from the establishment survey is published in two comprehensive data books—*Employment and Earnings, United States* and *Employment and Earnings, States and Areas*, and their annual supplements. More detailed information on wages and other aspects of collective bargaining appears in the monthly periodical, *Current Wage Developments*. More detailed price information is published each month in the periodicals, the *CPI Detailed Report* and *Producer Prices and Price Indexes*.

Symbols

p = preliminary. To improve the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.

r = revised. Generally, this revision reflects the availability of later data but may also reflect other adjustments.

n.e.c. = not elsewhere classified.

Schedule of release dates for major BLS statistical series

Series	Release date	Period covered	Release date	Period covered	MLR table number
Employment situation	September 3	August	October 8	September	1–10

Real Earnings	September 23	August	October 26	September	11–15
Major collective bargaining settlements	....	....	October 27	1st 9 months	33–34
Productivity and costs:					
Nonfarm business and manufacturing	....	....	October 28	3rd quarter	28–29

EMPLOYMENT DATA FROM THE HOUSEHOLD SURVEY

EMPLOYMENT DATA in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 60,000 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

Definitions

Employed persons are (1) those who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work because they were on layoff or waiting to start new jobs within the next 30 days are also counted among the unemployed. The **unemployment rate** represents the number unemployed as a percent of the civilian labor force.

The **civilian labor force** consists of all employed or unemployed persons in the civilian noninstitutional population; the **total labor force** includes military personnel. Persons **not in the labor force** are those not classified as employed or unemployed; this group includes persons retired, those engaged in their own housework, those not working while attending school, those unable to work because of long-term illness, those discouraged from seeking work because of personal or job market factors, and those who are voluntarily idle. The **noninstitutional population** comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy.

Full-time workers are those employed at least 35 hours a week; **part-time workers** are those who work fewer hours. Workers on part-time schedules for economic reasons (such as slack work, terminating or starting a job during the week, material shortages, or inability to find full-time work) are among those counted as being on full-time status, under the assumption that they would be working full time if conditions permitted. The survey classifies unemployed persons in full-time or part-time status by their reported preferences for full-time or part-time work.

Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the preceding years. These adjustments affect the comparability of historical data presented in table 1. A description of these adjustments and their effect on the various data series appear in the Explanatory Notes of *Employment and Earnings.*

Data in tables 2–7 are seasonally adjusted, based on the seasonal experience through December 1981.

1. Employment status of the noninstitutional population, 16 years and over, selected years, 1950–81
[Numbers in thousands]

Year	Total non-institutional population	Total labor force		Civilian labor force							Not in labor force

EMPLOYMENT, HOURS, AND EARNINGS DATA FROM ESTABLISHMENT SURVEYS

EMPLOYMENT, HOURS, AND EARNINGS DATA in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by 177,000 establishments representing all industries except agriculture. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

Definitions

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12th of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in manufacturing include blue-collar worker supervisors and all nonsupervisory workers closely associated with production operations. Those workers mentioned in tables 11-15 include production workers in manufacturing and mining; construction workers in construction; and nonsupervisory workers in transportation and public utilities; in wholesale and retail trade; in finance, insurance, and real estate; and in services industries. These groups account for about four-fifths of the total employment on private nonagricultural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. **Real earnings** are earnings adjusted to reflect the effects of changes in consumer prices. The deflator for this series is derived from the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W). The **Hourly Earnings Index** is calculated from average hourly earnings data adjusted to exclude the effects of two types of changes that are unrelated to underlying wage-rate developments: fluctuations in overtime premiums in manufacturing (the only sector for which overtime data are available) and the effects of changes and seasonal factors in the proportion of workers in high-wage and low-wage industries.

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received and are different from standard or scheduled hours. **Overtime hours** represent the portion of gross average weekly hours which were in excess of regular hours and for which overtime premiums were paid.

Notes on the data

Establishment data collected by the Bureau of Labor Statistics are periodically adjusted to comprehensive counts of employment (called "benchmarks"). The latest complete adjustment was made with the release of May 1982 data, published in the July 1982 issue of the *Review.* Consequently, data published in the *Review* prior to that issue are not necessarily comparable to current data. Complete comparable historical unadjusted and seasonally adjusted data are published in a Supplement to Employment and Earnings (unadjusted data from April 1977 through February 1982 and seasonally adjusted data from January 1974 through February 1982) and in *Employment and Earnings, United States, 1909-78,* BLS Bulletin 1312-11 (for prior periods).

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review,* December 1969, pp. 9-20. See also *BLS Handbook of Methods for Surveys and Studies,* Bulletin 1910 (Bureau of Labor Statistics, 1976).

NOTE: The industry divisions of mining; construction; tobacco manufactures (a major manufacturing group, nondurable goods); transportation and public utilities; and finance, insurance, and real estate are no longer shown. This is because the seasonal component in these is small relative to the trend-cycle, or irregular components, or both, and consequently cannot be precisely separated.

r = revised.

UNEMPLOYMENT INSURANCE DATA

National unemployment insurance data are compiled monthly by the Employment and Training Administration of the U.S. Department of Labor from monthly reports of unemployment insurance activity prepared by State agencies. Railroad unemployment insurance data are prepared by the U.S. Railroad Retirement Board.

Definitions

Data for **all programs** represent an unduplicated count of insured unemployment under State programs, Unemployment Compensation for Ex-Servicemen, and Unemployment Compensation for Federal Employees, and the Railroad Insurance Act.

Under both State and Federal unemployment insurance programs for civilian employees, insured workers must report the completion of at least 1 week of unemployment before they are defined as unemployed. Persons not covered by unemployment insurance (about 10 percent of the labor force) and those who have exhausted or not yet earned benefit rights are excluded from the scope of the survey. **Initial claims** are notices filed by persons in unemployment insurance programs to indicate they are out of work and wish to begin receiving compensation. A claimant who continued to be unemployed a full week is then counted in the insured unemployment figure. The **rate of insured unemployment** expresses the number of insured unemployed as a percent of the average insured employment in a 12-month period.

An **application** for benefits is filed by a railroad worker at the beginning of his first period of unemployment in a benefit year; no application is required for subsequent periods in the same year. **Number of payments** are payments made in 14-day registration periods. The **average amount of benefit payment** is an average for all compensable periods, not adjusted for recovery of overpayments or settlement of underpayments. However, **total benefits paid** have been adjusted.

[1] Initial claims and State insured unemployment include data under the program for Puerto Rican sugarcane workers.

[2] Excludes transition claims under State programs.

[3] Excludes data on claims and payments made jointly with other programs.

[4] Excludes data on claims and payments made jointly with State programs.

[5] Cumulative total for fiscal year (October 1-September 30). Data computed quarterly.

Note: Data for Puerto Rico and the Virgin Islands included. Dashes indicate data not available.

r = revised.

PRICE DATA

PRICE DATA are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base period (1967 = 100, unless otherwise noted).

Definitions

The **Consumer Price Index** is a monthly statistical measure of the average change in prices in a fixed market basket of goods and services. Effective with the January 1978 index, the Bureau of Labor Statistics began publishing CPI's for two groups of the population. One index, a new CPI for All Urban Consumers, covers 80 percent of the total noninstitutional population; and the other index, a revised CPI for Urban Wage Earners and Clerical Workers, covers about half the new index population. The All Urban Consumers index includes, in addition to wage earners and clerical workers, professional, managerial, and technical workers, the self-employed, short-term workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctor's and dentist's fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items is kept essentially unchanged between major revisions so that only price changes will be measured. Prices are collected from over 18,000 tenants, 24,000 retail establishments, and 18,000 housing units for property taxes in 85 urban areas across the country. All taxes directly associated with the purchase and use of items are included in the index. Because the CPI's are based on the expenditures of two population groups in 1972–73, they may not accurately reflect the experience of individual families and single persons with different buying habits.

Though the CPI is often called the "Cost-of-Living Index," it measures only price change, which is just one of several important factors affecting living costs. Area indexes do not measure differences in the level of prices among cities. They only measure the average change in prices for each area since the base period.

Producer Price Indexes measure average changes in prices received in primary markets of the United States by producers of commodities in all stages of processing. The sample used for calculating these indexes contains about 2,800 commodities and about 10,000 quotations per month selected to represent the movement of prices of all commodities produced in the manufacturing, agriculture, forestry, fishing, mining, gas and electricity, and public utilities sectors. The universe includes all commodities produced or imported for sale in commercial transactions in primary markets in the United States.

Producer Price Indexes can be organized by stage of processing or by commodity. The stage of processing structure organizes products by degree of fabrication (that is, finished goods, intermediate or semifinished goods, and crude materials). The commodity structure organizes products by similarity of end-use or material composition.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States, from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

In calculating Producer Price Indexes, price changes for the various commodities are averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1972. The detailed data are aggregated to obtain indexes for stage of processing groupings, commodity groupings, durability of product groupings, and a number of special composite groupings.

Price indexes for the output of selected SIC industries measure average price changes in commodities produced by particular industries, as defined in the *Standard Industrial Classification Manual 1972* (Washington, U.S. Office of Management and Budget, 1972). These indexes are derived from several price series, combined to match the economic activity of the specified industry and weighted by the value of shipments in the industry. They use data from comprehensive industrial censuses conducted by the U.S. Bureau of the Census and the U.S. Department of Agriculture.

Notes on the data

Beginning with the May 1978 issue of the *Review*, regional CPI's cross classified by population size, were introduced. These indexes will enable users in local areas for which an index is not published to get a better approximation of the CPI for their area by using the appropriate population size class measure for their region. The cross-classified indexes will be published bimonthly. (See table 19.)

For further details about the new and the revised indexes and a comparison of various aspects of these indexes with the old unrevised CPI, see *Facts About the Revised Consumer Price Index*, a pamphlet in the Consumer Price Index Revision 1978 series. See also *The Consumer Price Index: Concepts and Content Over the Years*, Report 517, revised edition (Bureau of Labor Statistics, May 1978).

For interarea comparisons of living costs at three hypothetical standards of living, see the family budget data published in the *Handbook of Labor Statistics, 1977*, Bulletin 1966 (Bureau of Labor Statistics, 1977), tables 122–133. Additional data and analysis on price changes are provided in the *CPI Detailed Report* and *Producer Prices and Price Indexes*, both monthly publications of the Bureau.

As of January 1976, the Wholesale Price Index (as it was then called) incorporated a revised weighting structure reflecting 1972 values of shipments. From January 1967 through December 1975, 1963 values of shipments were used as weights.

For a discussion of the general method of computing consumer, producer, and industry price indexes, see *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976), chapters 13–15. See also John F. Early, "Improving the measurement of producer price change," *Monthly Labor Review*, April 1978, pp. 7–15. For industry prices, see also Bennett R. Moss, "Industry and Sector Price Indexes," *Monthly Labor Review*, August 1965, pp. 974–82.
